The symptomatology is quite striking. In some cases there are a few premonitory symptoms, such as restlessness, refusal to nurse and a slight elevation of temperature; the chief symptom, however, is spontaneous hemorrhage. The site of this hemorrhage may be from any of the following sources: intestines, stomach, mouth, nose, navel, ecchymoses of skin, cracks of the skin, pressure-points, as heels and sacrum, meninges, genito-urinary tract and eyes.

As the hemorrhage persists, there is a progressive whitening of the child's skin and a gradual drying up of the tissues. The face becomes pinched; the muscles become weaker and weaker; the pulse becomes rapid, thin and weak; respirations are deep and sighing; the cry is weak, it may even be a whine; coma comes and death soon follows.

The diagnosis is very easy, as there is no other condition that even simulates this disease, except traumatic hemorrhage.

In hemorrhage of the gastro-intestinal tract, inspection of the stool in the diaper shows a black tar-colored mass with a pink fringe around the edge. The differential diagnosis of these conditions is of minor importance. The treatment is the same whether the case is one of hemorrhagic disease of the new-born, Winkel's disease, Buhl's disease, jaundice with hemorrhage or hemophilia. Brown and Swift divide these cases into three clinical types, namely, the umbilical, the seromucous and the purpuric, with a mortality of 60, 50 and 22 per cent., respectively. This was before the use of serum and direct transfusion of blood.

PROGNOSIS

The hemorrhage usually appears from the second to the fifth day of life. The earlier the onset of the hemorrhage, the more serious the prognosis. In luetic cases it usually appears from the seventh to the ninth day. One of the chief terrors in this disease arises from the fact that in half the fatal cases death occurs suddenly within twenty-four hours or less from the onset of the bleeding; hence, if the child is to be saved, it must have immediate attention. Townsend reports 32, in which 25 patients died and 7 recovered; 9 of those that died lived less than a day from the detection of the bleeding, and 4 lived only one day. It must not be forgotten, in the bowel cases, that the amount of blood that is vomited or passed by rectum does not represent the patient's entire loss of blood. The intestinal tract may be full of blood and the amount passed in the stool will be only a small percentage of the total blood lost to the baby.

The cases in which there is bleeding from the bowel are often quickly fatal, the entire clinical course being only a few hours; the shortest clinical course in my series was four hours from the discovery of the bleeding to the virtual death of the baby. Frequently the babe will nearly bleed to death into the bowel or stomach before any of the blood is passed by rectum or vomited. In the umbilical and purpuric types, the hemorrhages, being external, are discovered earlier, and the loss of blood can be accurately estimated. According to Dr. Jacobi, the total blood in a baby is equivalent to one-nineteenth of its body-weight.

Using this as a basis, a baby has approximately 1 ounce of blood to an adult's quart. Hence, a hemorrhage of 1 ounce in a new-born baby is equivalent to 1 quart in an adult.

TREATMENT

In the treatment of hemorrhage of the new-born, there are three indications: First, the hemorrhage should be stopped; second, the lost blood should be replaced; third, the infection should be overcome. Transfusion of live non-clotted blood meets all these indications in an ideal manner. Transfusion stops the bleeding at once, replaces the blood lost and gives the baby fresh complement and antibodies to aid it in overcoming any infection that may be present. Some of these cases are due to asphyxia and consequent fatty degenerations.

A well-transfused baby has more red blood-corpuscles than normal, each one capable of carrying oxygen to every portion of the baby's body, and this oxygen is available to prevent further fatty change and to remove that already formed. Direct transfusion of live, non-clotted blood from a healthy adult meets all the indications in hemorrhagic diseases of the new-born, better than any other method. Direct transfusion of blood will cure in practically every case. It is never too late to transfuse if there is still the slightest auricular beat, or even if the heart has apparently stopped for a short time; by means of a transfusion of blood the heart may be started again (Case 1). The patients who bleed from the bowel should be transfused early, because of the liability of sudden death from a massive hemorrhage into the bowel. Most surgical operations are of a destructive character and accompanied by a shock, which requires a certain amount of bodily vigor to overcome. Direct transfusion of live, non-clotted blood is not a destructive

TABLE 1.—DETAILS OF AUTHOR'S CASES

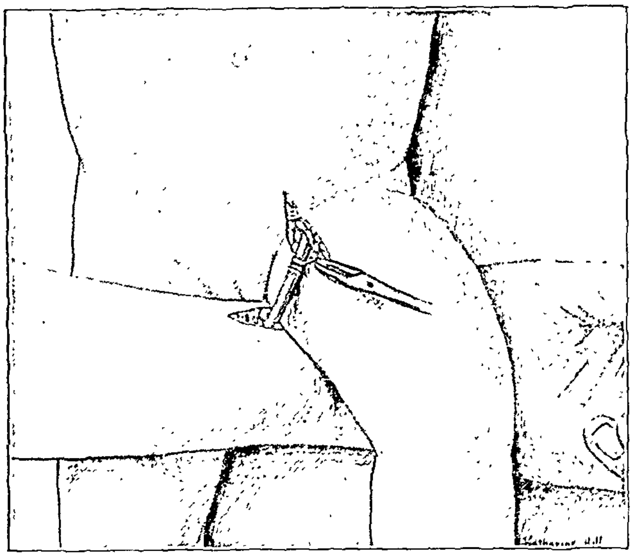
Case	No. of Children	Weight at Operation Lbs. Oz.	Age of Baby Hours	Source of Hemorrhage	Treatment Before Operation	Duration of Hemorrhage, Hours	Condition Before Transfusion	Condition During Transfusion	Condition After Operation	Remarks	Ultimate Results
1. Dr. DeLee	2	.. ..	48	Rectum; stomach	None	4	Almost pulseless; intense pallor; comatose	Heart not audible for 5 minutes	Very red; strong	Heart was heard about 15 seconds after transfusion was started. This babe was practically brought back to life. Gained 1 ounce per day for first seven days after transfusion	Recovery
2. Dr. Bellows	4	.. ..	34	Mouth; rectum	None	26	Anemic	Skin became red	Normal	Weighs 25¼ pounds at 22 months old, fine healthy boy	Recovery
3. Chicago Lying In Hospital, Dr. Horowitz	1	7 2½	9*	Bladder; circumcision wound	Clamps; sutures	24	Pale; very anemic	Became pink; first ear, cheek, general	Normal	Took the breast three-fourths hour after transfusion	Recovery
4. Dr. Woods	2	5 1	20	Mouth; rectum	Gelatin; horse-serum	5	Anemic; comatose	Color better; still stuporous	Somewhat stronger but not much	Luetic parents. Baby's blood contained staphylococci and gave a + Wassermann.	Death five days after transfusion
5. Dr. H. M. Stowe...	..	6 2	24	Circumcision wound	None	†	Very anemic	Color red; stronger	Excellent	Cesarean section baby. Ether used as anesthetic	Recovery
6. Dr. Gill	1	.. ..	72	Rectum; stomach	None	48	Very weak	Became red	Good	Delivered by high forceps. Progressed normally after transfusion	Recovery
7. Dr. Roberts	1	.. ..	72	Rectum	None	48	Anemic	Became red; Stronger	Excellent	Nursed mother one hour after transfusion. Now is a fine baby	Recovery
8. Dr. Bellows	2	4 ..	7*	Umbilical cord, mouth skin, finger-tips, heels, sacrum	Umbilical cord buried	48	Very weak; very anemic	Very red; stronger	Cried lustily; quite strong	First baby died of lues. Patient had condylomas, snuffles and macules on the skin	Death nine days after transfusion
9. Dr. Knapp	1	8 ..	10	Bowels; mouth	Horse-serum	72	Grave; almost gone	Gradually improved	Greatly improved	Passed old blood for two days, otherwise normal	Recovery
10. Dr. W. L. Ruggles..	7	5 ..	72	Frenum of tongue; intestine	Normal salt; horse-serum	48	Exsanguinated	Pulse aflicker; gasps at long intervals	Excellent	Regained original weight at age of 4 weeks; perfectly well. Bleeding from tongue ceased at once, the mouth filling with a dense black clot. This was removed and the area was dry.	Recovery
11. Dr. Piper	7	9 5½†	40	Bowels	None	12	Thirsty; restless; crying constantly	Became red; abdomen became prominent	Very good, gained 14¾ oz. in weight	Stools normal thirty hours after transfusion	Recovery
12. Dr. Cleary	2	.. ..	72	Bowels, stomach, mouth, subcutaneous	Horse- and human-serum	48	Poor; very anemic; very weak	Improved as blood flowed in	Excellent	Treated with human serum for 30 hours. Had massive hemorrhage and almost died before transfusion. Weighed 10½ pounds at 4 months	Recovery
13. Dr. Cleary	1	6¼ ..	36	Bright blood from bowels	Horse-serum	9	Restless; dried up; very anemic and weak	Red blood passed by bowel; improved	Good; color fine	Bright red blood by rectum on the table. No more red blood passed. Weighed 7½ lbs. at age of 20 days	Recovery
14. Dr. McQuarie	2	7¼ ..	96	Intestine	None	12	Pale; cold; unable to nurse; very feeble	Became red, then blue, then intense red all over	Fine; red all over as in scarlet fever	Nursed one hour after transfusion	Recovery
15. Drs. Marcusson and Dorland	1	.. ..	6*	Bowel	Gallic acid; adrenalin; stypticin by hypo	96	Very anemic; very weak; marked pallor; fed with medicine dropper	Became red; cried lustily	Very good; strong; nursed at once; no more blood	Continued to gain; nurses and in every way is strong and well; nursed immediately after transfusion	Recovery

* Days. † Unknown. ‡ With clothes.

operation; instead of inducing shock, the transfusion overcomes shock. The postoperative condition of the baby after direct transfusion of blood is very much better than the preoperative condition.

CLINICAL PICTURE

When first seen a bleeding baby is anemic, pale, weak, restless, passing tarry stools frequently and having a dried-up appearance. Later on the baby becomes limp and can hardly cry, and is as white as the proverbial sheet, blood is oozing from the mouth or from the navel, and there are purpuric spots scattered about more or less diffusely over the skin. The diaper is full of a black tarry mass, which may show red blood around the edges. During the progress of the transfusion, the child's color gradually becomes pink, then red, first on the lips and ears; then little pink spots are scattered diffusely over the body, and finally, after the baby is filled with blood, may become as red as an ordinary scarlet-fever patient. The hemorrhage from the various lesions cease as if they had been clamped with artery-forceps; by the time the transfusion is completed, the lesions are absolutely dry. In the wound that is made on the baby to dissect out the vein, one can note the formation of a firm, hard clot. When the wound is first made, the blood that flows looks like poor red ink. The coloring-matter seems to be in little particles floating in the serum. As the transfusion progresses, the blood becomes redder and redder, and finally the wound becomes filled with a firm, hard clot. Simultaneously with the color-changes in the skin, there is a great improvement in the baby's general condition. The cry becomes vigorous and he kicks with more strength; when the wound is being sewed, he makes a great protest every time the needle is passed. Finally, when the babe is taken back to his mother, he is strong enough to nurse and weighs from 8 to 14 ounces more than he did before the transfusion. After the operation, the baby nurses and sleeps quietly, the restlessness is gone; the temperature drops to normal, the old blood is passed out of the intestine in a day or two and the babe gains weight as fast as a normal babe, or even a trifle faster.



Position of baby and the arm of the donor in direct transfusion. The radial artery of the donor and the femoral vein of the baby are used for the transfusion, which is done according to the Crile technic.

MORTALITY

In my series of cases there have been no deaths from hemorrhage. Two patients died of syphilis, one five days and the other nine days after transfusion. My cases varied in severity from one in which the patient was practically brought back to life, to others in which there was less immediate danger. If we compare this mortality with that of cases treated by other methods, we find that the same types of syphilitic patients die and that in severe bowel cases the patients die as in most of the other types of cases that are treated late. Transfusion cures in these bowel cases and all the late cases provided it is done before the baby is actually dead. (In three cases in which I have been called I found the baby dead.) Direct transfusion of blood has cured after all other methods failed. My plea is to transfuse early and take no chances of a sudden hemorrhage before anything can be done, as almost happened to me in Case 12.

The *amount of blood received by the baby in Case* 11 was 14¾ ounces by weight. In Case 12 the baby was weighed just before the transfusion; twenty-four hours after the transfusion he weighed 15 ounces more. This represents 421.5 c.c. of blood in Case 11 and 428.5 c.c. in Case 12. Some may be inclined to doubt these weights, as at first glance they seem rather excessive. To confirm them I made the following experiment: A dog weighing 7½ pounds without any preliminary bleeding was transfused from a dog weighing 15 pounds. The time of transfusion was five and a half minutes. At the completion of the transfusion, the abdomen of the recipient was rather prominent, the mucous membranes of the mouth were very red, and the dog had gained 18 ounces in weight. The donor was practically dead at the completion of the transfusion. Hence, this small dog contained all of his own blood and all the blood from a dog twice as big as himself. The recipient recovered from the anesthetic and was in excellent physical condition, in no way the worse for having received this large amount of blood.

After transfusion, fresh blood disappears from the stool at once, showing cessation of hemorrhage; tarry stools may continue from ten to forty hours after transfusion, being the old hemorrhage gradually expelled. One of my patients the second day after the transfusion had one stool which contained a few flecks of bright blood (Case 1).

In hemorrhage of the new-born the patients are not hemophiliacs; they are not bleeders in after-life at all. All sorts of operations have been performed on these babies from one week to several months after the bleeding has ceased, and there has been no extraordinary hemorrhage. These children grow and become normal healthy persons. Rapidity of transfusion should be *considered carefully; if the blood is* allowed to enter the vascular system of the baby too rapidly, there will be a temporary dilatation of the heart and the baby will become blue about the face and on the feet and hands. When this occurs, the blood-flow should be stopped until the red color returns. Patient 5 had a double femoral vein, an anatomic anomaly that complicated the operation considerably. The smallest baby was Patient 8, weighing 4 pounds. In Case 1 the heart could not be heard for about five minutes before blood was transfused. The heart was heard a few seconds after the flow was started, and in a few seconds more the heart-beat was visible.

The father was the donor in ten cases, the mother's half-sister in one and a non-relative in three.

The blood-vessels used were the radial artery in seven cases and a forearm vein in seven cases on the donor; on the baby the femoral vein was used in four instances and the jugular in ten.

The duration of the transfusion varied from five to fifteen minutes. In the case that took fifteen minutes, Case 11, the father fainted, reducing his blood-pressure so low that it took longer to fill the baby with blood.

Table 2 shows the cases that have been reported in the literature. In their essentials they are all exactly like my own cases, details of which are given in Table 1.

† Two syphilitic patients; both patients died.

Three deaths and thirty-four recoveries.

CONCLUSION

Direct transfusion of blood stops the bleeding, restores the lost blood and aids in overcoming infection. Direct transfusion of blood has cured where all other methods have failed. Transfusion should be used early, but so long as there is a spark of life evident, it is never too late to transfuse.

The experimental part of this work was done in the Laboratory of Experimental Surgery of Northwestern University Medical School.

7 West Madison Street.

COMPOUND FRACTURES OF THE BONES OF THE EXTREMITIES *

W. L. ESTES, M.D., F.A.C.S.
Director and Physician and Surgeon-in-Chief of St. Luke's Hospital
SOUTH BETHLEHEM, PA.

This paper may be better followed and understood if at the outset its matter is indicated in the following postulates:

1. In civil practice a compound fracture is always not only a solution of the continuity of a bone, but also a lacerated wound of the soft tissues in continuity from the periosteum to, and including the skin.
2. Violence necessary to produce a compound fracture of the bone of an extremity must be very great; hence the traumatism is extensive. Commonly the bone is comminuted and the laceration of the soft tissues very severe.
3. Compound fractures are practically always infected wounds.
4. The management of these injuries must include the treatment of a fractured bone and the treatment of a more or less extensive infected lacerated wound of the soft tissues of the same area.

An examination of 2,089 fractures admitted into St. Luke's Hospital shows that 800 of these fractures were compound. In regions where large manufacturing establishments are located, and also where railroads are many and active, the relative frequency of compound fractures to all fractures is therefore 1:2.6, or 38 per cent. of the fractures.

The management of compound fractures of the extremities must resolve itself into two general considerations, namely, (1) the treatment of the general condition of the patient brought about by the injury; (2) the treatment of the injury itself.

A patient's reaction to these severe traumatisms depends on many individual peculiarities, on his environment and on the circumstances of the injury. Individual resistances to psychic shock, to "anoci-association," to loss of blood, must all enter into consideration. The horrors of a severe railroad or factory wreck and the conditions of the locale of the accident have also their effect. In short, a compound fracture, as every other disease or injury does, varies in every case, and should be treated as individual. The treatment must be adapted to the circumstances of each case, not the case adapted to any set method of procedure. This I consider a most important matter and I try to emphasize it on all occasions.

FIRST AID

The intelligence and skill of a practitioner in many instances, will be taxed to the utmost to meet the necessities of first-aid treatment of compound fractures. One cannot too much emphasize the importance of the proper initial treatment of these injuries. As I have said so often, the fate of the limb and perhaps the life of the patient depend on the manner of the first aid.

First, the general condition of the patient must be gauged as accurately and rapidly as possible. Stimulants may be necessary and should be used (alcohol is not a stimulant and should not be given). An analgesic should be given; as a rule, morphin, in full dose, combined with a small dose of atropin and given hypodermatically, I think, is the best. The control of hemorrhage should be sedulously sought. If practicable to avoid it, a tourniquet of any kind should not be used to control hemorrhage in these cases. If nothing else avails and a tourniquet must be used it ought to be applied some distance away from the seat of fracture. In cases of compound fractures of the bones of the legs, for instance, the tourniquet should be applied to the lower third of the thigh, or if of the bones of the forearm, to the lower third of the arm. An elastic constrictor is best and much safer.

Hemorrhage may as a rule be controlled and at the same time another indication, namely, protecting the wound, may be carried out, by packing the open wound with sterile gauze or any sterile fabric, placing thick compresses of sterile cotton wool or any other clean material over the wound and bandaging it firmly in place, from the extremity, over the wound, and to at least six inches above the fracture. Great care must be used to prevent any further soiling of the wound. No effort should be made to "set the bones," and in no case should a projecting end or fragment of bone be allowed to recede under the skin, unless means are at hand of making adjustment and proper fixation of the bones and limb, and unless the projecting bone and the edges of the external wound have been carefully cleansed and disinfected beforehand. Death has often resulted from the infection occasioned by unnecessary manipulation of a wound without previous sterilization of the hands. Never should a finger be thrust into any wound unless the finger and the wound have been previously cleansed and sterilized.

---

* *Read by invitation before the New York State Medical Society.*

Careful fixation "in the position assumed by the injured limb" should be employed, unless it is clear that the ends of the fragments are where they will surely do more damage unless their position is changed. The patient should then be transported where he may receive proper permanent dressing and such treatment as his case will require.

The surgeon should try to determine at the very beginning of his responsible management of every case of compound fracture, the following points:

I. What will be the best treatment of this particular injury, considering: (1) the individuality and the physical condition of the patient; (2) the environment of the patient; (3) the actual condition of the injured member.

II. What method of treatment or operation will most likely result in the shortest time of disability of the patient and give him afterward the best functional result?

PERMANENT TREATMENT: I. SPECIAL CONSIDERATIONS

1. *Individuality of the Patient.*—Before everything else I would place the consideration of the patient himself. That is to say, I would learn, if possible, not only the actual physical condition of the patient ith regard to the tolerance of the trauma, its effects id the extent and degree of the local injury, but also is habits, his temperamental peculiarities and his gen-al health and resistance. Obviously, it would be ighly improper to treat an exhausted patient, or a ery old person, or a very young child, or a diseased and weak individual, as one would treat a vigorous adult in prime condition.

Thus, after assuring himself that hemorrhage has been thoroughly controlled and that the patient's suffering has been relieved as far as practicable, the surgeon should at once make a thorough physical examination of the patient. He should carefully note all organic lesions, indications of dyscrasias, improper or delayed development, or signs of marked senility. The blood-pressure should always be taken. The immediate subsequent procedures should be determined by this physical examination.

If the patient is in a condition of exhaustion from psychic shock, loss of blood, or "anoci-association," or if his blood-pressure is very low, all extensive and tedious manipulations and operations must be delayed. If he is very old, a long operation with continued anesthesia will be dangerous. Also any method of treatment which will require long confinement to bed should be avoided. Bone repair in most dyscrasic individuals is very slow and always uncertain. Methods must be varied and adapted to meet the indications of the patient's condition.

2. *Environment of the Patient.*—The surroundings of the patient will have a very important bearing on the treatment to be employed. When at all practicable, a serious compound-fracture case should be treated in a first-class hospital. It is as a rule far better for the patient to endure the hardship of a one- or two-hour journey in order to reach a hospital than to be subjected to the discomforts and deprivations he would have if he were treated at his home, unless he were very rich. A surgeon is sadly handicapped in trying to treat such cases outside of a well-equipped hospital.

3. *The Actual Condition of the Injured Member.*—As was said in the beginning, a compound fracture is always a complicated injury of very grave severity, and is practically always an infected wound. One must always bear this last fact in mind and treat the case with a full recognition of the importance of thorough cleansing and disinfection of the wound, and especially of thorough drainage.

General anesthesia is usually necessary for the proper examination, handling and dressing of a compound fracture of one of the principal long bones. This is particularly desirable, not so much for the relaxing effect, as to obviate the dreadful pain of the examination and fixation. Compound fractures when not comminuted are much easier to reduce and fix in place than simple fractures.

There is one point in regard to cleansing and disinfecting the injured parts I wish to note, that is, the great value of tincture of iodin for its rapid and very efficient action in disinfecting soiled skin and wounds. One must remember that iodin is of little use over skin which is moist and sodden. In such conditions it will not penetrate but will blister. The surface of the skin to which iodin is applied for disinfecting purposes should be dry. Therefore cleanse the skin of the limb about the wound with benzin, ether or turpentine, and alcohol, then dry carefully and paint it with the tincture of iodin.

Every compound-fracture case will require some operative procedure. In rare instances measures for proper drainage only will be necessary; but in most instances much more will be required.

One must decide at the time of the first permanent dressing:

1. Can the limb be saved?
2. If saved, will the limb be left in a condition for practical use?
3. Will it be best for this patient to run the possible risk of his life, endure a period of long disability, have probably a permanently disabled limb, or will it be best to amputate and thus practically assure his life and shorten the time of his disability by at least one quarter?

1. *Conditions Determining Amputation rather than Attempts at Conservation.*—*A.* If the skin has been so crushed or lacerated that it is evident that at least three-quarters of the periphery over the fracture will slough, and the muscles beneath are badly lacerated or comminuted, amputation will be inevitable.

B. If there has been a circular or annular destructive pressure on the whole periphery of the limb, at the site of fracture or very near it, amputation will be necessary.

C. If in a case of compound fracture with a serious annular laceration of the skin the subjacent muscles are badly comminuted, it will be best to amputate.

D. If the injury has been produced by tremendous pressure, as of a car-wheel or heavy pillars of iron or steel, the limb may have the skin of its whole periphery, or nearly all of it killed but not divided, but the muscles beneath will be torn across and the bone comminuted. Such injuries require amputation.

E. If the main blood-vessels are torn across in the irregularly jagged way common in these injuries, amputation will be necessary. I do not think anastomoses or transplants of blood-vessels will succeed in this class of injuries. The laceration of one of the chief vessels when there are two in an extremity does not necessitate amputation. The large nerve trunks will stand much more injury than blood-vessels and may successfully be sutured, unless a long segment of the nerve be destroyed.

F. If the bone or bones are comminuted so that the fragments are loose and deprived of periosteum, requiring the loss of as much as 6 cm. (3 inches) of the shaft, this, together with the lacerations of muscles and skin always present in such cases, will require amputation.

2. *Probable Final Condition of the Limb.*—This is a very important matter and might profitably be considered with the third condition, namely, the best thing for the individual patient. Undoubtedly limbs might be saved which would be quite useless and sometimes positively in the way afterward. Again, for some persons even a useless limb might be considered best if it could be left in a painless condition. A man who has to earn his living by activity and manual labor should be placed in a different category from a man whose livelihood depends on sedentary work requiring very little or no activity. Also for some persons the long confinement and disability resulting from the treatment of a serious compound fracture might be so irksome and indeed disastrous that they might prefer an amputation, and this would be best.

With regard to the danger to life there is no question that conservation is much more hazardous. Analysis shows that in 8.8 per cent. of the cases of compound fractures treated conservatively, the patients died. The average mortality after single major amputation is but 4.54 per cent. The average disability from compound fractures of the femur and both bones of the leg is thirteen months. That of amputation is not quite five months. Of course, this means that the patient may get about, and through the use of an artificial limb may return to a life of comparative activity and much usefulness, though rarely will he be able to return to his former occupation, if it were a laborious one.

Having decided to attempt conservative treatment of the extremity, the first consideration should be to cleanse the wound and surrounding skin. Disinfection (sterilization) of skin and wound should be done thoroughly, especially the ends of the fragments if one or more has penetrated through the skin. Some extension apparatus, such as the Lemon or Lambotte extension bar, is very useful in these cases. Reduction is usually not difficult, on account of the facts that one may see or directly feel the ends of the fragments and guide them by forceps or some kind of lever, and that the muscles are usually so badly lacerated that they do not offer the resistance which is nearly always present in cases of simple fractures.

The fingers should be kept out of the wound as much as possible. I think there can be no doubt that infection is most apt to occur from finger manipulation in the wounds. By a little practice and experience one will learn to perform all the necessary manipulations with the aid of instruments.

Frequently the wound made by the injury, by a little extension or direction, may be used as a way of approach to the bone. The muscles usually are so much lacerated that an incision of the skin and fascia only is necessary. In short, the injury has frequently prepared a way to the bone and if any further incision is necessary it may be so made as to assist in another cardinal object, namely, drainage. One objection to the open method of treating fractures of the long bones of the extremities, that is, the necessary wound, has in compound fractures been removed by the traumatic opening of the tissues.

Direct fixation of the fragments is nearly always best. A rigid splint or plate applied directly to the bone is better than wiring the fragments. In selected cases a nail or nails may be used. I cannot understand the objections and warnings of some otherwise very up-to-date and experienced surgeons against the use of plates in compound fracture cases. My experience and conviction have always been that these are the very cases which demand plates. No valid objection can be offered to sterile fixation instruments unless they in some way harm the fragments. If a proper plate is used in the proper manner it does not injure the bone.

Even if the wound cannot be thoroughly sterilized (and it is exceedingly difficult to do this), suppuration and the evils of infection are diminished locally by a proper metallic plate. Researches at Johns Hopkins Hospital over twenty years ago proved the inhibiting influence of many metals on bacterial growth. Iron and steel are not thus active, as they oxidize too readily, but silver, copper and nickel and their alloys are active inhibitors.

Since 1886 I have used a plate made of Wessel silver, and I have used Wessel silver pegs for many years to fasten this plate to the fragments. I am sure this plate has always seemed to exercise a beneficent effect in compound fractures even with active suppuration present. Besides, fixation relieves pain and further injury which might be caused by the excursions of the ends of the unfixed fragments. After fixing the ends of the fragments one must decide about suturing the lacerated soft tissues. As was said before, blood-vessels are injured in such a way in compound fractures that not only are long stretches absolutely destroyed, but the vasa vasorum are thrombosed for some distance on either side of the evidently destroyed area. The vessel-walls will not bear tension or constriction. I think, therefore, that vascular anastomoses and implantations cannot be used. This is all the more true because these cases are always infected more or less, and vascular anastomoses do not succeed except in sterile fields. Arteries and large veins, therefore, should be ligated and not sutured. Divided nerve-trunks may be successfully sutured in these cases and this should be done when necessary. Tendons and muscles may also be sutured, but not when they would seriously impede or block proper drainage. The lacerated fascia and skin should be pared along the margin of the original wound and then be closed with interrupted sutures, sufficiently close to prevent gaping of the wound, but not so as to interfere with free drainage.

Drainage is all important. There will have been very considerable hemorrhage. In very painful lacerated wounds the muscular coats of the local arteries are usually in a condition of almost tetanic spasm. Relief of the pain and complete rest of the limb will be followed by relaxation of the arteries; the result will be that small vessels not perceived during the operation will bleed after the wound is closed. Considerable oozing will always occur. In addition to the oozing blood the opened lymph-spaces will pour out quantities of serum. All this fluid should be released and drained out of the wound. Unless this is done, disaster will almost surely occur. The reasons for this are so well known it is not necessary to go further into this.

A very important point with regard to drainage is that it should always be done in such a way and the drains so placed as to avoid all tension and harmful pressure in the wound. This is particularly important when the skin has been torn from the fascia and turned back as a flap, or raised up by a large effusion of blood. Most of the blood-supply has been cut off from the skin in such cases, and any pressure or much tension on the skin will cause a slough. Multiple incisions should be made through the skin and drainage by canalization (without the use of any drain material) should be employed. The incision should be so placed as to assist in relieving tension.

Thus, the bone having been fixed, the lacerated soft tissues sutured, the wound closed and proper drainage provided, a masse dressing of dry, sterile, absorbent material should be applied with fairly firm pressure, and over all a gypsum splint with strips of flexible wood or light metallic strips worked into it, should be molded, and so placed as to give support and some elasticity to the dressing. If all goes well the dressing may remain on for three weeks, then be changed and a similar one applied. Usually all drainage-tubes and gauze packs may be removed and left out at this first dressing. Also it is my custom at this dressing to remove the pegs which hold the plate, unless it be a fracture of the femur. If the wound has not closed over it the plate may also be removed. If the plate is well enclosed and buried by union of the flaps no effort should be made to remove it. As was said before, the plate does not cause any irritation if allowed to remain; on the contrary it seems to inhibit bacterial growth and hastens union of the wound.

PERMANENT TREATMENT: II. AS TO RESULTS

What method of treatment or operation will most likely result in the shortest disability of the patient and give him the best functional result? This determination is meant to apply only when conservative treatment is to be attempted. The indications for amputation have already been given. The question resolves itself therefore, practically, as it is intended to apply it in this instance, into: Will it be best to use direct fixation to the fragments, if so, what kind?

I have recently analyzed fifty-one cases of compound fractures treated in my clinic in St. Luke's Hospital. These cases are taken from the records of the last five years and represent the cases which could be traced and the final results definitely determined. They represent the following classes of compound fractures.

Femur	8 cases
Tibia and fibula	15 cases
Tibia alone	10 cases
Patella	2 cases
Metatarsal bones	2 cases
Humerus	4 cases
Radius and ulna	7 cases
Radius alone	1 case
Ulna alone	1 case
Humerus, radius and ulna	1 case
Total	51

Direct fixation of the fragments was made in 35 cases, of which 28 were plated and 7 were wired. In 13 cases external fixation only was used; 3 patients were moribund when admitted and died within a few hours after admission. (No special treatment and not enumerated further.)

The cases in which plating was done were the following:

Femur	7 cases
Tibia and fibula	12 cases
Tibia	5 cases
Humerus	4 cases
Total	28

The cases in which wiring was done were the following:

Tibia and fibula	2 cases
Radius and ulna	3 cases
Humerus, radius and ulna	1 case
Patella	1 case
Total	7

The external fixation apparatus was practically the same in all the cases, namely, a reinforced gypsum splint carefully molded over a large masse dressing of sterile gauze and cotton wool. The average length in days of confinement in bed in the various injuries was:

Forearm cases	6 days
Humerus cases	11 days
Leg cases	28 days
Femur cases	38 days

The average time in days spent in the hospital in the various injuries was:

Forearm cases	23 days
Humerus cases	48 days
Leg cases	53 days
Femur cases	69 days

The average length of time the patient was away from work, that is, until he returned to his occupation, was six months in leg fractures and thirteen months in fractures of the femur. For fractures of the upper extremity the time of disability has not yet been thoroughly worked out, but it appears to be about four months. All except three of the patients who had direct fixation were operated on within forty-eight hours. Two cases of compound fracture of both bones of the leg were plated on the fifteenth and eighteenth day after injury respectively, because the fragments could not be kept in place. The case of compound fracture of the humerus and both bones of the forearm was wired on the tenth day after injury, also because by other means the fragments could not be kept in apposition.

Though compound fractures should always be regarded as infected wounds, it is noteworthy that it is recorded of these cases that suppuration occurred in only two of those which were fixed by direct application to the bones. One patient with compound fracture of the femur, plated, had a streptococcic infection, but made a good recovery; one patient with compound fracture of the humerus, radius and ulna, wired, had suppuration from a mixed infection, but also made a good recovery. Not one of the patients in the direct fixation cases died.

RESULTS

In the forty-eight cases treated, there were two deaths, both from septicemia. In one case of compound comminuted fracture of the femur with very extensive injuries to the soft tissues, amputation should have been done, but the patient refused amputation and died on the fourth day from acute sepsis. The other case was one of prolonged septicemia from a mixed infection in a man who had a compound fracture of both bones of the leg, for which no direct fixation was done. The mortality was 4.16 per cent.

One patient with compound comminuted fracture of the bones of the leg with dislocation of the ankle-joint had a mixed infection; destruction of the joint and tarsus followed and an amputation became necessary. All but one of the forty-six patients who left the hospital had useful limbs, that is, the one previously noted on whom amputation was done. Of these patients, 40.32 per cent. have returned to their former work and report that they notice no disability.

Roentgenograms which were taken show the conditions of the bones during and after recovery. Roentgenograms in cases of compound fractures are taken (1) after the first permanent dressing; (2) after the fixation plates have been removed; (3) when the union seems complete; (4) after the patient has returned to his occupation.

The number of cases is too small for any set conclusion with regard to the treatment of compound fractures, but certainly in this small series direct fixation has produced much quicker recoveries and far better results than the former conservative methods. It will be noted that not one of the thirty-five patients in whom direct fixation was applied to the fragments died. They all made good recoveries. In the smaller number of cases (thirteen) in which the fragments were not fixed by direct splints on the bones (three hopeless cases are not considered in this reckoning), two patients died of sepsis.

Roentgenograms show that fragments which have been plated together remain in better adjustment than those which have been wired, and the anatomic results are better, except in cases of fracture of the patella There is less pain after the use of plates than when wire is used, and union results more quickly. It seems, therefore, that compound fractures of the long bones are best treated by rigid splints applied directly to the bones. I believe that the Lane plates are not the best for these cases, however. Experience of other surgeons has shown that in cases of compound fractures the Lane plate must nearly always be removed. Usually it is difficult to get at the screws and then it becomes necessary to use a general anesthetic and to make a considerable additional wound in order to remove this plate; whereas a plate fastened by pegs which project through the skin may be released simply by withdrawing the pegs, and if it is necessary to remove the plate this may be done simply by utilizing one or two of the punctures remaining after the peg has been removed, which requires no anesthesia.

A further consideration is the time of disability. My cases show that the average time of disability for compound fractures below the knee was six months and for those above the knee, namely, fractures of the femur, thirteen months. The use of plates thus shortens the time of disability in leg cases by about four months and of the thigh cases, five months. Of the patients, 40.32 per cent. are known to have been able to resume their former occupations. No doubt a number of others were likewise able to do this, but I could find only this number after a year or more from the time their treatment was ended.

805 Delaware Avenue.

THE ROUTINE TREATMENT OF PUERPERAL SEPSIS

JOHN COOKE HIRST, M.D.
Associate in Obstetrics, University of Pennsylvania, Department of Medicine
PHILADELPHIA

It is obvious that not every case of fever in the puerperium is of septic origin. Engorgement of the breasts, constipation, nervous perturbation, malaria, syphilis typhoid and other adynamic fevers are some of the many causes of fever entirely separate and distinct from sepsis due to bacterial invasion. It must also be remembered that there are two distinct varieties of sepsis: sapremia due to saprophytic infection and putrefaction of pieces of placenta, membranes, decidua or blood-clot in the uterine cavity, and septicemia due to actual bacterial invasion, most often streptococcic, of the endometrium and adjacent structures, frequently invading directly the blood-current and by far the most dangerous variety.

Sapremia answers promptly to a single evacuation of the uterus and disinfection of the genital canal, with possibly a few supplementary daily intra-uterine douches. Septicemia means a long, hard fight, not infrequently a losing one, against many complications.

It is not my purpose to discuss the various means by which bacteria can be introduced into the genital canal of a parturient patient, except in one particular. One of the causes spoken of is auto-infection, in which the germs are already present, and no one, except the patient herself, is responsible. This is a comforting thought, but merely means that she is suffering from one infection (gonorrheal, for instance) which reduces her resisting power to a supplementary infection by any pathogenic micro-organisms which may be in the lochia, and is really not auto-infection at all.

DIAGNOSIS

The diagnosis of sapremia is easy. There is a moderate fever, considerable subinvolution of the uterus and a foul brown or brownish-red discharge. A single evacuation and disinfection of the uterine cavity is usually sufficient.

The diagnosis of septicemia is not so easy, in its early stages. The general symptoms are chills, rapidly rising temperature, rising pulse-rate and a physical depression often out of all proportion to the other symptoms.

The local symptoms, on which the diagnosis usually rests, are a foul discharge (though this symptom may be entirely absent), reddened and edematous labia, a false membrane formation and a subinvoluted, boggy, tender uterus. Pelvic exudate is not often an early symptom, though common enough in the later stages. In doubtful cases, certain methods of precision may be employed as aids in diagnosis. Leukocyte-counts will usually be higher than in any other form of fever in the puerperium, but in some of the worst cases a low count, showing poor resistance, will be obtained. Cultures taken from the uterine cavity, by the Doederlein tube, or cultures directly from the blood-current, are often valuable aids, but unless they are taken with the strictest aseptic technic, and submitted to a competent bacteriologist with adequate facilities for their culture and diagnosis, they become the reverse of precise.

PREVENTION

The preventive treatment of sepsis may be summed up in two words: surgical cleanliness. The nearer an obstetric case is handled like a major surgical one, the less will be the danger of infection.

The patient's room should be sunny and well ventilated. The patient herself should take a bath at the onset of labor and empty the lower bowel by an enema, and the pubic hair should be shaved or at least clipped close. The bed should be made fresh and adequately protected by pads (preferably of nursery cloth, which can be boiled and dried). The water should be boiled for half an hour at least, and trust should not be placed in antiseptic solutions. Instruments should be boiled, or if injured by boiling, soaked for at least an hour in 1:1,000 mercuric chlorid or 1:20 phenol (carbolic acid) solution, being previously wrapped in gauze or a towel. Bougies, for instance, unless wrapped, will float on the surface.

The sterilization of sheets, gauze, towels and cotton is often a matter of some difficulty. If access to a hospital sterilizer can be had, steam under pressure in an autoclave is the most efficient. A Rochester portable steam sterilizer is quite satisfactory, however. but the time-honored custom of baking in the kitchen stove is a delusion and a snare. Unless the materials are so charred as practically to disintegrate, they are not sterile. and when so charred they are of course useless. The gauze and cotton commercially prepared in glass jars have always proved satisfactory. That in cardboard cartons is open to suspicion. For sheets and towels a safe method of procedure is to have them freshly washed and then ironed with an iron not quite hot enough to scorch them.

The physician should scrub his hands just as carefully as if about to operate, and in addition should wear a sterile suit, or at least a gown, and boiled rubber gloves. It has been proved many times that parturient patients are more subject to infection by the exanthems than at other times, so the care of these patients and obstetric ones do not go together.

The nurse is governed by the same general rules as the physician, being scrupulously clean in the handling of the patient and her pads, etc. The so-called practical nurse on whom we must so often depend is a problem. Her intentions are of the best, but her execution is bad. If one can be found who does not have an ineradicable desire to test the temperature of water by wiggling her fingers in it; who does not keep the patient's pads in an open pasteboard box under the bed, or who is without a habit of impressing into service as a pad every piece of cloth she can find, before it is thrown away as useless, that one is the exception and as such a jewel beyond price.

TREATMENT

The first step in the curative treatment of septicemia is the local disinfection of the genital canal, commonly but erroneously spoken of as curettage — an operation more abused than any single one in obstetrics. It is indicated in nearly every case, and properly done, is productive of much good — improperly done, it may be homicidal.

The patient is placed on a table (an ordinary kitchen-table answers the purpose very well) and not in her bed, as remaining in bed adds greatly to the difficulty. An anesthetic is not necessary. The vulva and vagina are carefully cleansed with cotton and tincture of green soap and sterile water, followed by a douche of 1:4,000 mercuric chlorid solution.

The anterior lip of the cervix is caught by a double tenaculum and pulled down. This straightens the axis of the uterus, makes access to its cavity easier and lessens the danger of perforation of the posterior wall. The uterine cavity is then irrigated through a two-way catheter, and an Emmett curettement forceps is inserted and any masses of tissue contained in the cavity or hanging like stalactities from its walls are removed. The instrument usually sold under the name of placental forceps makes a first-class club, but as a surgical instrument it has its limitations. It is much too long, heavy and clumsy. If any curetting at all is done, a dull, broad-bladed curet should be used, and not a sharp one, and under no circumstances should any force be used. The so-called placental augers are outrageous instruments and should never be used. In the vast majority of cases complete evacuation can be secured by the placental forceps alone, and any curetting is unnecessary. The proper type of placental forceps is much more effective than the finger, and should be used in preference. When the operator is satisfied that the cavity is empty, a second intra-uterine douche is given, and the uterine cavity is not packed unless there is bleeding sufficient to warrant it.

Should the temperature not subside, or having subsided rise again, there is no need or justification for a second evacuation or, to use the abused term, curettage of the uterine cavity. Intra-uterine douching alone is advisable, and the best solution for this douche is one of tincture of iodin 2 drams, 95 per cent. alcohol 8 ounces, and sterile water sufficient to make two quarts. This douche given once daily is sufficient. Nothing is gained by douching more frequently. It is needless to add that the two-way catheter should have ample provision for return flow, to prevent any fluid passing out through the fallopian tubes.

To the form of treatment just described there is only one contra-indication — phlebitis; but as it is impossible to know in the early stages that the pelvic veins are infected and to be sure that the uterine cavity is empty, the lesser of two risks is taken by proceeding with the disinfection. Should, however, a sharp rise of temperature follow the disinfection, no further local treatment, even an intra-uterine douche, should be countenanced.

The routine use of vaginal or uterine douches, in the absence of symptoms justifying their use, and purely as a preventive of infection, is not to be recommended. The douches destroy Doederlein's bacilli, normally resident in the vagina, and by thus preventing the action of the acid vaginal secretion, remove one of the dependable barriers to infection.

In the general treatment the diet is of great importance. An easily digested, largely liquid diet should be given in quantities as great as the patient can assimilate. Alcohol should be given to the point of tolerance, from 8 to 10 ounces of whisky a day being not an unusual dose.

Stimulants are often required, as indicated by the heart-action. A patient with a pulse of under 110 does not ordinarily require stimulation. If it passes this limit, digitalin and strychnin are the most reliable drugs to be used. Artificial leukocytosis, theoretically beneficial, can be produced in one of several ways, as by hypodermic injection of 2 drams of 2 per cent.

watery nuclein solution twice daily, or the formation of a fixation abscess.

The latter recommendation is based on the fact that if a general infection becomes localized, improvement frequently results. Two drams of turpentine injected under the skin of the abdominal wall will produce an abscess which is all that can be desired. What success this treatment has had is probably due to an increase of leukocytes, but my results with it have not made me enthusiastic as to its advantages over less painful methods.

Hypodermoclysis or enteroclysis, on the principle of increasing the body-fluids and washing the blood, are worth a trial but not too much to be depended on. Enteroclysis seems to give as good results as hypodermoclysis, and is much more convenient. Two quarts of salt or sugar (1 dram to the pint) solution are given at a time.

The use of serums and bacterins is at present the subject of as much discussion as any single point in the treatment of sepsis. When the serum was first marketed it was hailed as a specific cure; too much was expected of it and naturally the results were disappointing. This much we have found as to its availability: When it is given early and in sufficient doses, beneficial and sometimes brilliant results can be expected. When it is given late, the results are disappointing. The minimum dose is 80 c.c., given hypodermically every six hours; 100 c.c. is better, but the small doses of 10 or 20 c.c. are waste of time and material. The serum must be fresh, and it will not stand transportation for great distances. It is an expensive form of treatment, because of the large doses required. In desperate cases it can be given intravenously, and by this method I have secured immediate improvement in a case when the hypodermic method of administration for forty-eight hours had produced no effect whatever. I have not seen anaphylaxis from these large doses, or any other untoward effects. Occasionally patients seem benefited by the injection, in addition to the antistreptococcic serum, of from 5 to 7 ounces of normal human blood-serum, secured from a healthy donor, once daily. This is worth trying when the results from the antistreptococcic serum have not been satisfactory. Much of the criticism against the use of serum has been based on insufficient dosage and late administration, either or both. When it is given in doses of from 320 to 400 c.c. in twenty-four hours, it is a valuable aid in the treatment of sepsis, though it cannot be hailed as a cure for sepsis *per se*.

The use of bacterins has not been so satisfactory even as the serum. They are chiefly indicated in localized infections, and are nearly if not quite useless in the general blood-current infection. The best results have been obtained in gonorrheal arthritis complicating the puerperium. Here again large doses, from 250 to 500 million or more, must be used, and either autogenous or polyvalent cultures may be employed.

Colloidal silver has been largely used abroad, but is of doubtful utility. It can be used as an inunction of from 5 to 10 per cent. argyrol ointment, or the intravenous injection of from 3 to 5 c.c. of a 2 per cent. collargol solution, repeated at twenty-four-hour intervals for three or four doses. The inunctions, though they may not prove beneficial, are at least harmless; the same cannot be said for the intravenous injections, as alarming collapse has followed their use. There is still a great deal of doubt as to the favorable action of either plan.

There is no purpose in this paper of discussing the surgical treatment or the complications of puerperal sepsis, with one exception (phlegmasia alba dolens), as this falls more in the line of specialism and hospital treatment. Every physician should, however, be familiar with the indications requiring abdominal section, in a case of sepsis. Briefly stated, continued septic symptoms, plus the development of an abdominal mass, palpable above the symphysis or Poupart's ligament, demand surgical interference. Infiltration of the bases of the broad ligaments does not require abdominal section, as 90 per cent. of these cases undergo spontaneous resolution, and the rest can be opened, if needed, through Douglas' pouch. The explanation of this abdominal mass is found to be almost always a cornual abscess, pointing toward the peritoneum. I wish to emphasize the advisability of operation for these cases. I am aware that in many places surgical intervention is deprecated, as these cases are said to be hopeless. Without operation they are indeed doomed, as the abscess will rupture into the peritoneal cavity. With operation and proper drainage (which is the main factor in success), 90 per cent. of them can be saved. In the last ten years, at the Maternity of the University of Pennsylvania, the mortality in 165 of these operations was fifteen, or 9.6 per cent., and this in a class of cases that without operation are hopeless. Rapidity of operation, removal of only what is diseased, putting in only enough ligatures to stop the bleeding, leaving the broad ligaments gape, drainage by a glass tube in Douglas' pouch out through the lower end of the abdominal incision, with the pelvis packed full of gauze and the end of the gauze emerging alongside the glass tube, and active stimulation are the factors influencing success. The glass tube is sucked out every twenty-four hours and removed in five days; the gauze is slowly removed over the next five days, and the sinus then drained by a rubber tube. Vaginal drainage is useless in these cases and will reverse the mortality figures. The whole subject of the surgical treatment of puerperal sepsis is a most complicated one and it is not my purpose to touch on it further in this paper.

The commonest complication which the general practitioner meets is phlegmasia alba dolens, or milk-leg, and because of its relative frequency deserves some discussion. It begins late, from ten to thirty days post partum, with pain in the calf, usually the left, and some swelling. A moderate fever lasts for a short time, and the swelling extends until the whole lower leg and not infrequently the thigh are greatly increased in size. The vein can often be felt as a tender cord down the inner surface of the thigh.

Treatment consists in elevation, applications of equal parts of lead-water and alcohol, painting ichthyol over the course of the vein, or application of a saturated solution of magnesium sulphate, and the patient must be kept as quiet as possible, in bed, until the temperature has been uninterruptedly normal for at least ten days. The greatest danger is pulmonary embolism, and prognosis must therefore be guarded. The danger of embolism is greatly increased by too early activity or by massage, which should never be used. Often considerable stimulation is required, as the disease is depressing and asthenic in tendency.

A much rarer form is cellulitis of the thigh, which tends to suppuration of the connective tissue, and is treated like cellulitis in any other part of the body.

Abscesses in the phlebitic variety are not unknown, occurring most often in the popliteal space, but it is the tendency to embolism that must make our prognosis guarded, and make us forbid the patient to leave her bed until the fever and local tenderness have entirely subsided, and limit her activities, when up, until the swelling has practically disappeared.

1823 Pine Street.

THE PSYCHANALYST AND THE COMMUNITY *

TRIGANT BURROW, M.D., Ph.D.
Assistant in Psychiatry, Johns Hopkins Hospital
BALTIMORE

In the midst of the current discussion of psychanalysis, many aspects of the psychanalytic trend have been brought into view. The aspect, however, which to me seems by far the most vital but which has as yet received the least consideration is the relation of psychanalysis, and therefore of the psychanalyst, to the community.

There still persists, not alone in the lay, but also, unfortunately, in the medical mind, a wide-spread misapprehension in regard to the larger social and ethical implications of psychanalysis. It cannot be said that this misapprehension is due altogether to the mistaken interpretation of the dissenters; to a large extent it is due to the tendency of certain of the accepted adherents of the Freudian school of psychology. But wherever the blame should be placed for this misconception of the position of psychanalysis in relation to the ethical values of the community, it seems to me that it should now be the privilege, if not the obligation, of the psychanalyst to make clear the significance of his position to the body social, and to state in no disputable terms on what grounds he bases it.

The sphere of the psychanalyst is restricted for the most part to the study and relief of disorders embraced under the unhappy designation of functional nervous diseases or psychic disorders. It is, of course, justly acknowledged that the psychic equation of a patient enters more or less within the reckoning of every physician. Certainly it pertains conspicuously to the province of the specialist in nervous diseases — the neurologist, the medical psychologist. What is of momentous significance, however, in a comparison between the positions of these general trends of psychotherapy and the specific trend of Freud, is the wide difference in their fundamental method of procedure as determined by the essential disparity of the basic conceptions underlying these differing schools.

Of the numerous measures which human ingenuity has devised for successfully coping with nervous disorders, the aim hitherto of all of them has been essentially a remedial aim, that is to say the removal of discomfort. Relief, alleviation, cure is the exclusive idea. The underlying purpose of the conventional therapeutic regimen is conciliation, concession, propitiation. Thus, of the general schools of psychotherapy, the central idea is ease, palliation, support. The condition being one of discomfort, it must be replaced by one of comfort; and as the primary remedial object is easement, this must be sought with a view to the minimum incommodity to the patient. Hence conspicuous features of the more popular psychotherapeutic equipment are a quiet and remote domicile, conditions of isolation, rest in bed, attendant nurses, soporifics, and incidentally an occasional visit from the physician whose chief resources consist of a persuasive optimism combined with a gentle sympathy and a tactful evasion of aught that might in the least savor of unpleasantness to the patient.

I do not wish to disparage such a method. It possesses an undoubted therapeutic value. But whatever its remedial virtue, the fact is not to be blinked that, in the main, the method is designed with a view to the delectation of the patient. It is largely a program of concession. It is parleying and indirect. It temporizes and conforms, is diplomatic, cautious. It is a program that is encumbered with considerations of etiquette, rather than a direct and untrammeled scientific approach to the understanding and adjustment of the disorders at which it aims. The physician makes no real demand on the patient, but on the contrary directs all his ingenuity toward making him comfortable; thus the aid which a patient receives through such a mode of treatment is to a large extent rendered him on his own terms.

The position of the psychanalyst demands a directly contrary course of procedure. Here the situation admits of no compromise, no evasion, no attitude of indulgence. The policy of the psychanalyst is a robust one, and he outlines it without mitigation or cavil. Simply and directly, however considerately, he explains to the patient the psychologic meaning of his disorder in accordance with the psychanalytic interpretation, and informs him of the bearing of faulty mental habits and adaptations on the causation of nervous processes. The physician explains the essential disharmony at the root of these disorders; the irreconcilability of contending mental and emotional influences within the personality, pointing out the inherent conflict thus embodied in neurotic disorders. He further explains that a true adjustment may be made only through an honest recognition of the vital unconscious trends with which his personality is now blindly and inadequately contending. At the same time he frankly tells the patient that the process through which the requisite adjustment is to be made entails difficulty, discomfort and personal sacrifice on his part, and he does not disguise from the patient *his* responsibility in this effort of readjustment.

While not unsympathetic to the suffering of his patient, the psychanalyst makes clear that his is no maudlin or sentimental sympathy, such as would surround the patient with the soft and ineffective ministrations of external attentions, but that his sympathy is virile and adult and allied to what there is within the man of courage and honest purpose. And so the psychanalyst makes clear his position that for him "cure" means a thorough and unflinching acquaintance with one's innermost self, that cure is the attainment of an undistorted vision of life without regard to personal comfort or edification, and that the mind which is torn with inner doubt and discord is prepared to accept terms of peace with itself only when it has been brought to see things in their unembellished truth.

---

* Read before the fifth annual meeting of the American Psychopathological Association, Albany, N. Y., May 6, 1914.

Such is the position of the psychanalyst, and from this position he does not stir.

Realizing then that the symptoms of the neurotic patient are but the social gossamers beneath which he seeks to hide his natural outline, the psychanalyst proceeds to strip away these artificial draperies and address himself to the naked inner man. This is not an easy task. It is not easy by reason of its very nature. As the symptoms of the neurosis have been devised by an ingenious unconscious as a measure of defense against the bugbear of reality, the patient will seek no less ingeniously to maintain this defense against all encroachments.

So, from the outset, it is understood that patient and physician are entering earnestly and resolutely on an endeavor involving mutual responsibility and sacrifice.

When the psychanalyst has at last divested the personality of its artificial mantle, and views the natural man; when we have stripped away the husks of pretense and have dared to look unafraid on the contour of the actual; what we find universally to be the purpose, the real motive of all this elaborate and painstaking mechanism of insincerity and disguise is an ancient and indigenous *egotism*. Egotism is the effort to see things as we would have them, rather than as they are. Egotism is therefore no respecter of truth The *wish* is its sole criterion, for egotism is allied with the unconscious, with the primary, pleasure-principle, the original phase of psychic life with its immediate, hallucinated satisfactions.[2] It is egotism which leads us to choose what is pleasant in preference to what is true. It has been wisely said, "the truth hurts." It is so much easier to be beguiled with flattery and blandishments than to subject oneself to the searching light of self-criticism.

Thus it is egotism that lures men into the rosy path of irresponsibility. To follow it, however, is to take the path that leads finally beyond the bounds of organized society toward disintegration and madness, for *insanity is nothing else than the unmeasured sway within the personality of this disorganizing principle of egotism.* A recent writer, in a penetrating essay on Cervantes' classic portrayal of the mad Don Quixote, acutely discerns this underlying motive of the hero's insane delusions. "It is", the author says, "Don Quixote's irrational determination to believe as he wants to believe, rather than as the facts warrant," that is the cause of all his madness. "As Don Quixote more and more indulges his delusions and further departs from strict intellectual and moral integrity and truth, more and more he is alienated from his kind, more and more he is a lonely figure, less and less can any one help him. There is no longer any exchange of opinions between himself and others, only his own exaggerated opinions asserted dogmatically. He resents every dispute, every assertion which differs from his own, so that by and by his companions withdraw their converse."

It is this same egotism — this obstinate "determination to see the world *as it is not*, but only as he wishes it to be" which is the besetting fallacy of the neurotic personality. We maintain, however, that while not less deep-seated and obdurate, the egotism of the neurotic individual is somehow incompatible with something better within him. He seems imbued with a finer intellectual insight, a deeper sensitiveness to life's values. Some innate truth endows him with a higher moral criticism, so that instinctively he opposes a barrier to egotism's sensuous appeal, and so the insincerity and untruth into which his native egotism has decoyed him is to such a personality wholly intolerable, and he experiences the intensest mental suffering in consequence of the moral conflict which an enforced resort to such artificial protections has occasioned him. He can no longer find satisfaction in the popular appeasements of the body-social, but becomes more and more deeply introverted, withdrawn and inhibited, until at last his life has become so crippled and confined as to be no longer livable.

This description offers a rough character-interpretation of a frequent type of neurotic personality.[3]

It is the aim of the psychanalyst to lead such a personality out of his prison of repression and ineffectiveness by means of a patient and honest study of himself With consideration and respect the psychanalyst traces one by one the causes which have led to his isolation and repression. He leads the patient to a gradual realization of the inherent egotism—the latent unconscious *wish*—that has lain back of his symbolic disguises. Thus the personality is led little by little to an ever-deepening renunciation of the immediate pleasure-satisfactions and to the gradual attainment of a correspondingly broad conscious adaptation.

Let it not be thought, however, that we can inculpate on the charge of egotism the neurotic alone. After all we are of one tissue. We have but to look about us at the so-called normal persons composing the community to see that life masquerades no less under the disguise of social make-believes than under the symbolic subterfuges of the neurotic individual. The difference is that the artifices of the social community, being collective, unite its members, so to speak, by a common language, while the neurotic isolates himself through the extravagance of his metaphors. For the usages which commonly pass current are unacceptable to him. He refuses to accept life on the terms of popular indorsement. Rejecting the criteria of the majority, he stands on a life-and-death principle, and from his self-immolating choice popular subscription cannot swerve him.

What is the difference here? What is it that thus differentiates the neurotic, in his gloominess and withdrawal, from the average good fellow with his cheery complacency? The difference is merely that the neurotic assumes a deeper disguise. His concealment is more subtle. The symbols to which he resorts possess an organic antiquity. They are esoteric, elemental. It is thus that he separates himself from his normal social congeners.

Observe, however, that the policy which leads to the neurotic's self-imposed ostracism differs only in degree from the policy of the community. For society is hysterical, too. Society too has its elaborate system of defense-mechanisms, its equivocations and metonymies, its infantile make-shifts and illusions. The difference is that society's counterfeits possess the advantage of universal currency, and so the record of its frailties is set down under the name of custom rather than of pathology. The psychanalyst well knows though that inherently the situation is the same here as with the neurotic individual. For in whatsoever way it is sought to soften the stern aspect of reality, whether through the artificial appeasements and irrationalities of the social polity, with its phantastic mythological beliefs and superstitions, or through the yet subtler assuagements of the neurotic personality with his vicarious conversions and distortions, back of it all and actuating it all is, as I have said, an inveterate and inherent egotism.

---

[2] Freud, S.: Formulierungen über die zwei Prinzipien des psychischen Geschehens, Jahrb. f. psychoanalyt. u. psychopathol. Forschungen, 1911, iii, 1. Burrow, Trigant: Conscious and Unconscious Mentation from the Psycho-Analytic Viewpoint, Psychol. Bull., 1912, ix, No. 4, 154.

[3] Burrow, Trigant: Character and the Neuroses, Psychoanalytic Review, 1914, i, 121.

I have said that egotism is the more comforting course. If we would judge how much more comforting is the course of egotism, we need only reflect on the part it plays in the complex of activities which we call life. Consider for a moment to what extent the criteria by which we live are colored by egotism. Consider the part that egotism plays in our restless social, commercial and political activities. Consider to what extent the aspiration which we call religion is imbued with the egoistic hope of ultimate rewards and satisfactions.

And more tragic still, consider how often the activities we call scientific — that is, the supposedly sincere inquiry into truth — are actuated by an egotistic spirit of pride and self-assertion. Think how even here this organic and inveterate pleasure-principle asserts itself in human affairs to the detriment or undoing of honest purpose!

When we regard the deeper, more biologic aspects of human life — the interests and demands which arise from the sphere of the sex instincts and emotions — we find that here egotism is at its source, for it is one with the primary pleasure-affects in which the impulse of sex has its genesis.

Egotism is precisely the enemy of human progress against which the psychanalyst levels his aim. Under whatsoever sham egotism thinks itself most safely concealed, it is here that the psychanalyst directs his attack.

The task of the psychanalyst, therefore, is the readjustment of the neurotic patient through a process of self-elimination. It is his task to replace caprice with logic, emotion with reason, temporary satisfaction with permanent truth. The psychanalyst then takes his stand on adult characterologic ground. He recognizes that the abnegation of immediate selfhood is the highest attainment within the ethical nature of man, that the subversion of the primary, infantile pleasure-mode is the supreme renunciation.

We contend that since a great part of the beliefs and customs of the community have at heart the same underlying motive as actuates the symptoms of the neurotic patient with his organic evasions and substitutions, namely, an inherent egotism, the trend of the psychanalyst not only aids, in its reeducative influence, the individual, but also makes for a better and a healthier community. For the psychanalyst would utilize this force resident in the onward effort of mental evolution. He would direct to better uses this impulse of self-attainment which lies at the source of the manifestations which we call life, for with the attainment of consciousness the possibility is opened for converting this genetic life-force into a constructive and a purposive principle. With the gradual enlarging of consciousness it has become more and more adapted to social and ethical ends. Thus through the sublimating process of mental growth, egotism becomes diverted into self-devotion.

Life is wrought of aspiration; conduct is begotten of desire. Back of the restless energies of men there is this elemental instinct of attainment which constitutes the driving force of humanity itself—"humanity old, untruthful, deluded, wandering among a thousand cheats, clinging to outworn customs and beliefs, pretending to nobilities not its own, lending itself here, there, everywhere among a thousand falsehoods; humanity with its ineffectual virtues, its imperfect vision;" and yet for all its frailty and folly, for all its silly self-delusion and pitiful egotism, the deeper the psychanalyst applies himself to the study of human motives and to the interpretation of human life, the more clearly he discerns within this same humanity the deeper forces, making for order and continuity, which lie at the heart of life's processes.

The psychanalyst, therefore, who rightly appraises his work cannot but be deeply sensible of the honesty and the dignity of his endeavor, and of its wide social usefulness, for his efforts are allied with the forward progress of the race.

ANEURYSM OF THE SINUS OF VALSALVA

WITH REPORT OF TWO CASES

W. ATMAR SMITH, M.D.
CHARLESTON, S. C.

Although a search through the literature does not seem to substantiate the fact that aneurysm in this situation is common, it undoubtedly impresses one that the lesion is sufficiently frequent for the clinician to keep in mind.

FREQUENCY

The frequency of this aneurysm is difficult to compute accurately. Among the "special features" pointed out by Osler[1] are the statements: "It is often latent, causing sudden death by rupture into the pericardium. It is a medicolegal aneurysm met with in coroners' cases." Possibly because of this a large percentage of cases do not get into the records.

Cattell and Steele,[2] in reporting a case of aneurysm of the sinus of Valsalva, state that it is a very rare pathologic lesion, their case being the first in 2,000 necropsies. In 3,108 necropsies Bosdorff reports two. In the Middlesex Hospital Reports, containing protocols of 3,030 cases, there were two of aneurysm in this situation. Thus in 8,138 post-mortems only seven were found.

In 1840 Thurman collected twenty-two aneurysms affecting the aortic sinuses. In 1874 Durand reported twenty-two. Cattell and Steele, from whose monograph many of these data were obtained, collected twenty-one reports of cases up to 1898. I have found in the literature but seventeen cases between 1840 and 1903. It is impossible, too, to be sure whether or not some of them were not included by the authors mentioned above.

Sibbs collected 632 reports of cases of aneurysm of the arch, eighty-seven of which involved the sinuses of Valsalva. This was quite the largest percentage of occurrences found and is not generally borne out by other observers. In 120 cases of aneurysm of the arch reviewed by Cattell and Steele, only seven were found in this situation.

---

[1] Osler: System of Medicine, Ed. 8, p. 851.
[2] Cattell and Steele: Tr. Philadelphia Path. Soc., 1898.

Recent literature on the subject is very meager. There is a record of but three cases between 1905 and 1912.

These data would tend to confirm the view of the infrequency of this lesion, but it is entirely possible that the record, although the best we have, is not a true index of its real occurrence.

The sinus most often affected seems to be the right anterior; this is explained by Gray by the fact that the regurgitation of the blood takes place chiefly against the anterior aspects of the vessel.

Sinusal aneurysm may terminate in one of several ways. It may rupture into the pericardium. It may rupture into one or more of the cavities of the heart, the vena cava or the pulmonary artery. Of the twenty reports of cases collected by me, in two the aneurysm perforated the right auricle, in one the left ventricle and pulmonary artry, in one the pericardium and in five the pulmonary artery.

It has been stated that rupture does not lead to immediately fatal results, but death occurs most often from fatty degeneration of the hypertrophied myocardium. The aneurysm not rarely causes a relative dilatation of the aortic ring and leads to death from cardiac failure.

ETIOLOGY

The lesion occurs according to most authorities in young adults; as Osler puts it, "most frequently among young syphilitics." Of my cases, in only eleven were ages stated; four were in the third decade, four in the fourth, one in the fifth and two in the sixth. The lesion predominates in the male. In only one case in the literature could I find a woman affected. This is rather striking in view of the fact that the two cases, a report of which follows, were in young women.

Krzywicki states that the causes of aneurysm of the Valsalvian sinus are atheroma, increased pressure affecting points of least resistance, and syphilis. Roubier and Bouget concur, but they are "certain that syphilitic aortitis presides in these ectasias." "Peacock thought that certain of these aneurysms were due to congenital malformations which observations by Devic and Savy seem to confirm."

The majority of observers, however, recognize syphilis as the most potent etiologic factor.

REPORT OF CASES

Before considering the symptoms and signs of this lesion, I would first report the two cases coming under my observation, as they illustrate fairly well the usual manifestation of this condition.

Both of these cases occurred at the Roper Hospital under the service of Dr. Robert Wilson, Jr. Both patients were young negresses, aged 17 and 26, respectively, and both showed evidences of syphilis. The cause of death in both instances was venous stasis. In the first case there was dilatation of the aortic ring; in the second, perforation into the pulmonary artery. These cases, added to those previously collected, make twenty-two in all, six of which perforated the pulmonary artery.

CASE 1.—L. W., colored girl, aged 17, was admitted to hospital, Oct. 24, 1913, complaining of cough which began in the previous summer and persisted to the present; shortness of breath, weakness, pain under left nipple and edema of feet and legs. Latter symptoms began two weeks before and grew progressively worse up to the time of entrance. Past history negative. Physical examination revealed scars over tibiae, swelling of feet and legs, hurried and difficult respiration, rapid irregular pulse, wavy pulsations over precordium, especially at base. Thrill at base was most distinct over second and third intercostal spaces on the left of the sternum. It was impossible to decide whether this thrill occurred during systole or diastole, but it probably occurred during both. Apex was displaced downward and to the left. Cardiac dulness was increased to right and left of sternum. A loud humming "saw-like" murmur was heard over precordium, but with greatest intensity in third left interspace about 2 inches from sternum. In this location the bruit was extremely loud, of a high pitched rasping quality, and distinctly to-and-fro in character. At this site could also be heard a rather sharp snap, resembling a very accentuated closure sound. Because of the irregular heart-action and the peculiar murmur, it was impossible to determine during what part of the cardiac cycle it occurred. Roentgenoscopy revealed a great hypertrophy of both chambers, especially of the right ventricle.

The patient died November 19, with gradual rupture of compensation.

Necropsy.—General anasarca. Ascites, 750 c.c. Right pleural effusion, 500 c.c. Hydropericardium, 200 c.c. Chronic mitral valvulitis with dilatation of orifice and insufficiency. Dilatation of tricuspid orifice. Chronic aortic valvulitis with contraction of leaflets, dilatation of orifice and insufficiency. Sclerosis and atheroma of aorta with dilatation of atheromatous patch in right sinus of Valsalva, producing a saccular aneurysm of the sinus large enough to admit the end of the thumb and causing further dilatation of the aortic ring. General cardiac hypertrophy with chronic interstitial myocarditis, sclerosis of coronaries, parenchymatous and fatty degeneration of myocardium with general dilatation. Chronic passive congestion in other parenchymatous organs.

CASE 2.—B. L., colored woman, aged 26, was admitted to hospital, Feb. 27, 1914. Hysterectomy had been performed one year ago. Since then patient has been well except for occasional headache and feeling of dizziness, until Jan. 1, 1914, when symptoms of present trouble appeared. These consisted of cough, feeling of fulness in chest, dyspnea and edema of ascending type. The physical findings in this case were very similar to those in the preceding one. There was a greater degree of respiratory distress, more marked edema and the pulse was regular, but the most important difference was the absence of the loud closure sound which was so well marked in Case 1.

Roentgenoscopy revealed a large heart with pronounced distention of the right side.

Necropsy.—General anasarca. Papular eruption on forehead. Scars of old ulcer on right leg. Operative cicatrix in midline of abdomen. Excess of pericardial fluid. Mitral valves thickened but sufficient; atheroma and sclerosis of aorta with dilatation of atheromatous patch in right sinus of Valsalva producing aneurysm which projects through septum into pulmonary artery, perforating by two small openings behind the corresponding pulmonary valve. The sac admits the index-finger. General dilatation and hypertrophy of heart with fatty and parenchymatous degeneration of the myocardium.

DISCUSSION

It is not always possible to explain physical signs from the point of view of pathology, but we should try to do so, that our observations may be of value in future experiences. In the first case the striking signs were the loud to-and-fro "saw-like" murmur and thrill, the cardiac hypertrophy, especially of the right ventricle, the precordial pulsations and the so-called "closure" sound. There were probably several conditions responsible for the murmur, for, besides the aneurysm, there was an aortic insufficiency and a valvulitis of the mitral orifice causing insufficiency there. The cause of the cardiac hypertrophy is therefore obvious. The closure sound was probably diastolic and due to congestion in the lesser circulation.

The murmur in Case 2, in which there was perforation, can be accounted for by the to-and-fro passage of blood during the two phases of the cardiac cycle from aorta to pulmonary artery. It is easily conceivable that the churning of the blood caused thereby would produce the thrill. The hypertrophy of the right ventricle was caused by the increased quantity of blood in the pulmonary circulation due to the leak from the aorta.

The majority of other symptoms exhibited by these patients were simply those of failing compensation. It should be recalled that death in both cases was due to the effects of the aneurysm, namely, myocardial degeneration, and not to rupture.

DIAGNOSIS

In neither case cited was the diagnosis made ante mortem. In the first the youth of the patient, the peculiar murmur, the pulsations and thrill, with the valve-sound heard loudest over the pulmonary area and the right ventricular hypertrophy shown by the Roentgen ray were strongly suggestive of patulous duct of Botalli. In fact, we did not feel that this condition could be thrown out in spite of its rarity. We felt reasonably certain that mitral stenosis was present even if there was no persistent ductus to account for part of the signs. This proved incorrect.

In the perforating case we felt that here too there was a strong possibility of mitral stenosis playing a part in the findings. This was suggested by the hypertrophied right ventricle. Aneurysm of the heart wall was considered by one of the observers because of the precordial pulsations, the thrill and murmur.

It will readily be seen that the diagnosis of aneurysm of the sinus of Valsalva, perforating or otherwise, presents almost insurmountable difficulties. In fact, I have found no case on record in which it was stated that the correct conclusion was reached ante mortem. W. F. Wade in 1861 reported a case of aneurysm of the aorta arising above the valves and perforating the pulmonary artery and right ventricle in which the diagnosis was made before death. This is the nearest approach to the condition rightly interpreted.

There are no signs particularly peculiar to the lesion. The aneurysm may remain latent until rupture. In a case reported by Ralfe the signs were increased precordial dulness, double bruit at base and a faint systolic murmur at the apex. In a case by Stokes in which the sac ruptured into the conus arteriosus of the pulmonary artery, there was a thrill over the sternum and a double murmur heard best over the left base, but heard all over the chest even by the patient himself. In F. P. Henry's case, in which the aneurysm also opened into the pulmonary artery, the signs were dulness in left infraclavicular region, pulsation and thrill in the second left interspace, and a rasping systolic murmur over the same area. These findings and the findings in the two cases observed by me, although varying in many respects, are fairly constant in one particular: nearly all signs are referable to the pulmonary area or, rather, they are more marked in that situation.

In none of the cases contained in the literature was the Roentgen ray used as an aid to the diagnosis of this condition. This is important, as by means of roentgenoscopy any ectasias of the arch which might give identical signs could be discerned.

In conclusion it might be stated that aneurysm of the sinus of Valsalva, although comparatively uncommon, is not so rare as to be altogether devoid of clinical interest, and, although the diagnosis is infrequently justified, the lesion cannot be excluded in the face of the finding, in a young syphilitic, of a saw-like bruit and thrill most marked in the pulmonary area and a negative roentgenogram.

THE TREATMENT OF GALL-BLADDER INFECTIONS

WITH A REPORT OF TWENTY-SIX RECENT CASES *

JOHN H. GIBBON, M.D.
PHILADELPHIA

Although asked to discuss the "treatment of gall-stones," I have preferred to substitute the word "infections" for "gall-stones," as we now know that the primary cause of these stones is a microbic infection reaching the gall-bladder either through the blood or directly through the bile-passages from the intestine.

It is not my intention to deal minutely with the various operations which may be required in gall-bladder diseases, but rather to consider the indications for operative interference in these diseases and to present some of the pathologic complications which may arise when these indications are not heeded. I shall also say something about the mortality following operative treatment and its causes.

As a basis for my remarks I have taken the gall-bladder cases in which I have operated during the past six months and shall give a brief synopsis of each case. They number twenty-six, fourteen patients having been operated on at the Jefferson Hospital and twelve at the Pennsylvania Hospital. My figures might be more convincing if they were larger, but they represent a season's work and sufficiently illustrate every point I would like to make.

In considering the indications for operation, I would say that if one feels warranted in making a diagnosis of gall-stones or gall-bladder infection, he should also feel warranted in advising operation, unless there be some definite contra-indication. I am sure we all agree that if stones are present, no medicinal agent can dissolve them or make them pass through the ducts into the intestine. If the passage of stones does occur, it is Nature and not medicine that brings it about, and the passage of a few or many stones does not mean that all have passed or will pass. Case 12 illustrates this point well. While we are waiting and watching for our medicines to do the impossible, or while we are helping our patients to bear the repeated attacks of colic, the stones are increasing in number and in size, and the patient is running the risk of developing one of the serious complications to which gall-stones give rise and which are amply illustrated in the accompanying cases. When the stones are in the gall-bladder only and the drainage of that organ is not disturbed, an operation is a simple matter; but when

---

* Because of lack of space, this article is here abbreviated by omission of the case-reports. These, however, will appear in the author's reprints, a copy of which will be sent by the author on receipt of a stamped, addressed envelope.

the stones have passed into the common duct, when they are ulcerating through into the duodenum or colon, when they have blocked the cystic duct and given rise to an empyema, when the smaller bile-passages of the liver have become infected and jaundice is present, when the patient has developed an acute or even a chronic pancreatitis, or when the stones have by their constant irritation caused a cancer of the gall-bladder, the operation becomes at once more serious and sometimes hopeless. If we could cure only a few cases of gall-stones by medicinal means, there might be some excuse for postponing what is in most cases inevitable. Such postponement is not fair to the patient, and it is more honest to state the case fairly to him and let him decide what line of treatment he will have. He would be a fool who chose operation if told that by medical treatment he could be cured but cure by such means is not possible, and any sensible man or woman convinced of his medical adviser's honesty and ability will follow the advice of the latter. When the crisis or complication comes, the patients who may have suffered for years from sufficient symptoms to warrant surgical intervention, are often keener for operation than the surgeon is. What we need is to understand that to await serious symptoms — for instance, chills, fever and jaundice — is comparable to awaiting glandular metastasis and malignant cachecia before making a diagnosis of cancer. The time to look for and extinguish a fire is when we see the smoke and not when the house is wrapped in flames; then a child can make the diagnosis.

I have had in mind while making the foregoing remarks the cases in which the medical attendant has but little or no doubt in his diagnosis. In these cases it would seem that his duty was clear, but any surgeon's experience goes to show that the large majority of the patients are not operated on until some marked pathologic complication has developed. In most of the cases here reported some such complication was present, and the average duration of symptoms was over six years. The patients operated on during the most favorable period are usually those who come into the hospital wards — patients who can't afford to be invalids or to pay for medicinal treatment.

But what of the cases that do not show unmistakable signs of gall-bladder disease? Many can be diagnosed by obtaining a careful history and making an examination of the abdomen, especially at a time when the patient is having his greatest discomfort. The most constant, the earliest and the most persistent symptom of gall-bladder infection is what the patient calls "indigestion," which is manifested by a sense of "fulness" or "distention" in the upper abdomen, coming on especially at night and without any definite relation to the taking of food. He is apt to eructate quantities of gas and, if his discomfort increases to actual pain, he may vomit. The prompt relief which vomiting gives in these cases is of great diagnostic value. When the patient complains of gastric symptoms which are not characteristic of ulcer of the stomach or duodenum, the gall-bladder is often the cause of the trouble. An infected gall-bladder is nearly always tender and if tenderness is present, in connection with the type of indigestion referred to, then in the absence of symptoms suggestive of some other lesion, one is justified in holding the gall-bladder under suspicion and watching the patient carefully. If the gastric symptoms are persistent and if the tenderness is marked a diagnosis of gall-stones is warranted and operation indicated. If, in addition, the patient has sharp attacks of upper abdominal pain, referred or not to the back or right shoulder-blade, and accompanied and relieved by vomiting, one can feel more certain of the diagnosis. A transient jaundice following such an attack completes the picture. But jaundice is not essential for a correct diagnosis, it having been estimated that about 80 per cent. of the gall-stone patients operated on have never had jaundice. In the twenty-six cases here reported it had occurred or was present in fifteen. It seems unnecessary to repeat that if the patient has typical attacks of severe gall-stone colic, operation should be done, and the same applies to cases presenting evidences of serious infection of the gall-bladder or ducts. These are the cases of which I spoke in the beginning in which there is no doubt whatever as to the seat of the trouble.

Can we rely on the less typical symptoms given above? I believe if one is careful to eliminate other conditions, such as gastric or duodenal ulcer, chronic appendicitis, etc., the gall-bladder will be found to be the seat of the trouble. Is it not a fact that when one operates on these suggestive symptoms he often finds nothing? This has been my experience in some cases. I have studied very carefully my mistakes in diagnosis and with more care before operation and more experience, they are becoming much less frequent. The twenty-six cases reported here are all in which I have operated since Sept. 1, 1913, and I have felt that in none has the operation failed to develop the cause of the symptoms in the gall-passages.[1] I have previously discussed my errors in diagnosis. In one of the malignant cases here reported (Case 14) I made the mistake of first exploring the kidney, and in another (Case 19) the symptoms pointed to the kidney and the correct diagnosis was based on the Roentgen-ray findings alone. This was a case of calcareous gall-bladder with stones.

One point which I made in the former paper and should like to repeat here is that the gall-bladder can easily be the cause of very definite symptoms and still not contain stones, and that physicians often make the mistake of telling the patient he has gall-stones and are then unable to produce them. Although there may be diseased conditions in the gall-bladder and ducts amply sufficient to account for the symptoms, he is never quite satisfied because the expected stones were not found. He must be told that gall-bladder symptoms may result from other causes which demand operation just as much as the presence of stones. In this series there were two cases of acute cholecystitis without stone and three of chronic cholecystitis without stone. In my opinion these patients would have later developed stones had they recovered without operation.

This brief series of cases shows a variety of pathologic conditions which give some idea of what may be found in gall-bladder surgery. I regret that it does not contain a case of acute pancreatitis, which is so commonly caused by infection from the bile passages, and a case of rupture of the gall-bladder from over-distention, but I feel that what these cases do show is sufficient to teach the lesson that it is undesirable to allow patients with gall-bladder symptoms to drag along until some complication renders an operation imperative and often dangerous.

---

[1] In a paper read before the Massachusetts Medical Society, June 11, 1913; Boston Med. and Surg. Jour., Dec. 4, 1913.

There are 3 cases of acute gangrenous cholecystitis, in all of which the patients recovered; 2 cases of acute cholecystitis without stone, one developing two weeks after typhoid fever; 8 cases of stones in the common duct; 1 of stone in the ampulla of Vater requiring duodenotomy; 1 of calcification of the gall-bladder; 1 of abscess formation in the liver and spleen; 1 of subdiaphragmatic abscess two weeks after operation in a case of acute cholangitis due to stones in the common duct; 1 of cirrhosis of the liver; one of stones ulcerating into the colon; 20 cases of stones in the gall-bladder alone or associated with some of the enumerated complications, and 2 cases of cancer of the gall-bladder. The greatest number of stones (771) was found in one of the malignant cases.

In addition to the findings at operation the following points in the history of these cases may be of interest: In 5 cases there was a definite history of typhoid fever; in 12 it was definitely stated that there had been no typhoid fever, and in 9 cases no mention of typhoid is made in the history. Jaundice was present or there was a history of jaundice in 15 cases; no jaundice or history of it in 11 cases. The duration of the gall-bladder symptoms varied from one week to thirty-three years in 21 cases, was not given in 1 and given as "many years" in 4 cases. In the 21 cases in which the duration is definitely stated, the average is over six years. The youngest patient was 19 years old and the oldest 69 years; there were four patients between 19 and 30 years of age; four between 30 and 40; nine between 40 and 50; three between 50 and 60, and six between 60 and 70 years. There were eleven men and fifteen women.

There were five deaths as follows:

In Case 7 I drained an abscess of the liver and overlooked a large abscess in the spleen, which was found at necropsy. The patient was extremely ill and a diagnosis of stone in the common duct with suppurative cholangitis had been made. After removing a number of stones from the gall-bladder and draining a small abscess in adjacent portion of the liver, I thought I had found all the trouble. The patient died a few hours later.

In Case 8 there were about thirty stones in the gall-bladder and cancer of the gall-bladder with extensive involvement of the liver and glands was present. The patient died about a month after the operation.

In Case 18, a woman, aged 69, had declined operation when she was in good condition and did not consent until she had a severe attack of pain followed by jaundice, fever and a high leukocytosis. She was a dangerous risk, but I thought she would die if not operated on. I might have saved her by waiting for these acute symptoms of sepsis to subside, but my judgment was in favor of operation. She had stones in the gall-bladder and common duct and a quantity of sand and debris in the hepatic duct. She had had her first typical attack of gall-stone colic twenty-five years before and for two years had had frequent attacks.

Case 22 is similar in many ways to the preceding. The patient was 65 years old. I saw her when she was jaundiced and advised operation when she had improved. Before the jaundice had entirely disappeared she began to have chills and fever and I was obliged to operate when she was very septic. She had stones in the gall-bladder and common duct. She died from complete suppression of urine on the second day after operation without any abdominal symptoms and with a free drainage of bile. She had been having attacks of gall-stone colic for many years.

In Case 24, a man aged 45 was operated on when jaundiced but when acute pain and fever had subsided. He died seventeen days after the removal of stones from the common duct and gall-bladder, from an undiagnosed subdiaphragmatic abscess, which gave rise to no fever and no other evidences of its existance. At the necropsy the gall-bladder and ducts were in good condition.

It will be noticed that all of these deaths occurred in very ill patients; one with malignancy a month after operation; one with an abscess in the spleen; and three with acute cholangitis from stones in the common duct. With one exception, the malignant case, they were all jaundiced at the time of the operation.

In the uncomplicated case the risk of the operation is no greater than in any clean abdominal operation. In the cases of common-duct stone with cholangitis there is always the risk of death from sepsis, but the risk is greater without than with operation. Postoperative bleeding in the jaundiced cases can usually be prevented by the use of horse-serum; in all such cases the coagulation time should be taken and, if it is beyond the normal limit, it should be reduced by the injection of the serum. In this series of cases there was but one instance of bleeding, and this was not marked; it came on two weeks after operation when the patient was dying from a subdiaphragmatic abscess.

One is often asked what the chances are of gall-stones reforming after operation. My own conviction is that when all stones are removed and the gall-passages properly drained for about two weeks, recurrence is extremely rare. I can recall but two secondary operations in my own cases. In one case, I removed a stone from the common duct two years after my first operation, but here I felt it had been overlooked at the first operation, when I had removed 137 stones from the gall-bladder and 7 from the common duct. In the second case, that of a physician, there was a return of symptoms four years after the removal of 69 stones from the gall-bladder and I felt I might have left a stone which was causing the trouble. I was relieved to find 21 stones in the gall-bladder, for although I might have failed to obtain a stone in the ducts, I could hardly have overlooked 21 stones in the gall-bladder. This, I think, was clearly a case of redevelopment of stones. I removed the gall-bladder at the second operation.

I believe that this experience of six months in gall-bladder surgery represents pretty well what surgeons everywhere are finding and doing and that it teaches lessons by which we all may profit.

1608 Spruce Street.

A Suggestion for Applicator.—Because of the bulk of the applicator and the minuteness of the sinus, it is at times inconvenient to apply fluids with the ordinary cotton applicator. The so-called "sanitary pipe-cleaner"—everywhere obtainable, inexpensive and easily sterilized—is suggested to replace the cotton applicator. It is especially useful in fistulas and sinuses of the long bones.—Charles J. Rothschild, M.D., Fort Wayne, Ind.

GASTRIC HYPERTONY AND GASTRO-ENTEROSTOMY

WILLIAM J. MALLORY, M.D.
Instructor in Medicine in the George Washington University, Department of Medicine, and Attending Physician to the Outpatient Department of the University Hospital
WASHINGTON, D. C.

Every one is familiar with the brilliant results which usually follow a gastro-enterostomy for the relief of gastric ulcer. The patient makes a good recovery from the operation, the pain is relieved, vomiting ceases, weight is gained and the patient is clinically cured.

Occasionally, however, the operation is only a partial success or even an absolute failure. Vomiting recurs either while the patient is in the hospital or when the usual mode of life is resumed. Pain reappears and the patient may be as miserable as before. Indeed, the condition may be more serious, because of the stress of the operation, and the mental depression felt, as a result of what seems a failure of the most energetic measures to relieve the suffering.

This unusual course of events sometimes occurs when a correct diagnosis has been made, and the operation performed by a skilled and experienced surgeon. The following case-abstract will serve to illustrate:

A married woman, aged 28, who had one child in good health, was well until November, 1911, when she had a "cold." While recovering from this she drank some coffee one evening, this being the first food she had taken for two days. She became nauseated and vomited without pain, and without relief. This recurred after every meal for three weeks; then there was an interval of two weeks during which she ate what she pleased without nausea or pain, but she "did not feel herself." Following this, the vomiting recurred and continued constantly, that is, some food was vomited daily, until August, 1912, when she had an operation (gastro-enterostomy) performed. Vomiting again occurred while she was still in the hospital, and in September, 1912, she was worse than before the operation.

In August, 1913, a second operation was performed (adhesions broken up), which was followed by relief for about seven weeks. In October, 1913, vomiting again recurred almost daily. Roentgenoscopy revealed both the pylorus and the gastro-enterostoma functioning, but a bismuth residue after eight hours.

Obstruction was diagnosed, and at operation adhesions were found partly constricting the small intestine just below the gastro-enterostomy. These were severed and the patient did well until about two weeks after the operation; then on the day before leaving the hospital she began vomiting again.

Four other cases of this character might be reported, but this would be unnecessary repetition. That my experience is not unique is shown by the report of Zweig[1] of Vienna, who records twenty-seven such cases. That the unfavorable results are not necessarily due to faulty surgical technic has been repeatedly demonstrated by roentgenographic examination and actual inspection at a second operation. What, then, is the explanation?

The answer will be found in an understanding of the physiology of gastric motility and the disturbances of this function, which often precede and accompany gastric ulcer, that is, the *Vagotonie* of Eppinger and Hess,[2] hyperkynesis or spasticity of the stomach. While this reference opens the whole subject of visceral neurology, for present purposes it is sufficient to recall briefly the innervation of the stomach.

This organ receives nervous influences from three sources: it receives tonic or motor impulses through the vagus and inhibitory impulses through the sympathetic, and it may perform its functions fairly well when both splanchnics and both vagi are severed, being controlled under these circumstances by the local ganglionic plexuses of Auerbach and Meissner.[3]

In the condition described by Eppinger and Hess, there exists a state of affairs corresponding to excessive vagus stimulation, or a stimulative vagus neurosis, and while this manifests itself in other regions corresponding to the wide distribution of the nerve, our present concern is with the effects on the stomach. As one might suppose, both the motor and the secretory functions are increased. There is usually hyperacidity, pylorospasm and increased muscle tone with occasional spastic contraction. These patients say that they cannot take much food, the stomach feels full after even a meal, and there is a knot in the throat, cramp in the epigastrium, a feeling of tightness and constriction in the thorax, cardiac disturbance and the eructation of gas. Vomiting often occurs soon after eating, and is especially apt to be produced by excitement and anxiety.

Roentgenoscopy reveals a small stomach which fills with bismuth slowly, a mere thread trickling down toward the pyloric region, the stomach wall is tightly contracted around the contents, and the gas bubble in the fundus is small. Antiperistalsis and vomiting sometimes occur during examination.

The association of hyperacidity and pylorospasm with gastric ulcer is well known and needs no discussion here, but the effect of excessive tonicity and spastic contraction on the functioning of the stomach—after a gastro-enterostomy—is not so generally recognized. It is to this, therefore, that attention is especially invited.

Whatever may be the state of the stomach-muscle at other times, it is usually found relaxed at the time of operation; if it is not, relaxation is usually produced before the anastomosis is made. Now if the stoma is made of the usual size and in the correct location, it will functionate properly while the gastric motility is normal or even weakened; but if the neuromuscular mechanism is hypertonic and hypersensitive, this condition is not removed by an operation, and therefore as soon as the patient is in a position to receive the usual stimuli, that is, to take a full meal and resume the cares and annoyances which were present before the operation, spastic contraction of the stomach recurs. Not only is there pylorospasm as before, closing that outlet, but the contraction of all the muscle fibers in every direction greatly reduces the size of the surgical orifice and will at times close it entirely. Cramp, reverse peristalsis and vomiting recur, and clinically the patient is as ill as before the operation.

These symptoms often suggest obstruction, and a roentgenographic examination is made which may show both the pylorus and surgical orifice patent unless the examination is made when the stomach is contracted, that is, during an attack, when it will show a hypertonic stomach with no trace of bismuth passing through the new opening. A secondary operation will show the surgical opening patent and reveal nothing except a few minor adhesions such as occur after any operation.

If this explanation is the correct one, what is the remedy?

All ulcer cases should be examined for signs of vagotony, and if these are present, such cases should be regarded as unsuitable for surgical treatment; or if operation is imperative, as it sometimes is, suitable medicinal and hygienic remedies should be combined with the usual postoperative management.

The recognition of vagotony is not difficult if one will remember that there is such a syndrome, and examine the patient for the signs pointed out by Eppinger and Hess. These are the gastric symptoms already given, to which must be added either a few or all of the following: bradycardia, disturbances in the respiratory rhythm, a tendency to bronchial asthma, dermography, urticaria, local sweating, demonstrable "Head zones," low blood-pressure, pigmentation of the skin, eosinophilia, spastic constipation alternating with nervous diarrhea, and other minor signs of disturbances in the autonomous nervous system.

In vagotonic patients with gastric ulcer, it is not sufficient to perform a gastro-enterostomy and discharge the patients with advice to be careful about the diet; for although the operation may render local conditions more favorable for the healing of an ulcer, by providing for a more prompt discharge of food and the neutralization of the acid gastric contents by the bile, the important conditions underlying the formation of ulcer have not been removed, and if neglected may again annoy the patient and thus embarrass the physician.

Reference is again made to the irritable vagus. A surgeon, von Bergmann,[4] in his researches, has demonstrated that disturbances of innervation involved in secretion, motor and sensory function of the stomach constantly accompany both duodenal and gastric ulcer, and also that in the majority of cases, abnormal functioning in other organs dependent on the vegetative nervous system is plainly evident.

The conclusion follows that a neurotic general constitution and neurotic phenomena in the stomach and duodenum seem to be responsible for primary erosions, and also tend to prevent healing, thus establishing a vicious circle. Therefore drugs and other therapeutic measures acting on the vegetative nervous system are indicated in the treatment of gastric and duodenal ulcer *after* as well as *before operation.*

Infant Mortality in New York City.—According to a tabulation of W. H. Guifoy, registrar of records of the Department of Health, New York City, the death-rate per annum of children under five years has fallen from 96.5 per 1,000 in 1891, to 61.3 in 1901, 43.8 in 1911 and 37.3 in 1913. For the summer months—June, July and August—the death-rate of children under five years of age during the same period was 125.1 per 1,000 in 1891, 76.2 in 1901, 46.3 in 1911 and 38.8 in 1913. This reduction is believed to be due largely to the use of pasteurized milk, but doubtless also to other hygienic and sanitary measures adopted as the result of a constant agitation, legislation and the efforts of the health authorities.

THE NON-SPECIFIC ACTION OF A SERUM PREPARED ACCORDING TO THE METHOD OF BEEBE *

M. MILTON PORTIS, M.D.
AND
I. W. BACH, M.D.
CHICAGO

The treatment of exophthalmic goiter with a specific thyrotoxic serum, so that just the required amount of thyroid could be destroyed *in situ,* is desirable. Ten years ago, one of us (Portis) produced such a serum by injecting dogs' thyroids into goats. The cytotoxic serum so produced, although strongly thyrotoxic, was unfortunately also cytotoxic for the various viscera, especially the liver and kidney, and was markedly hemolytic. Stimulated by the reports from both the laboratory and the clinic, in the use of nucleoproteins derived from tissue cells as antigens, and the assertions that such serums are specific, we undertook the following work in December, 1912:

Normal human thyroid glands were obtained shortly after death and nucleoproteins were prepared according to the method of Beebe. These were injected into Belgian hares and rams in doses recommended by Beebe. Considerable difficulty was experienced in immunizing our earlier animals, for most of them died after repeated injections, with a severely toxic picture simulating anaphylaxis. After repeated failure, we at last succeeded in immunizing a ram. The technic of the preparation of the nucleoprotein material used, and the manner of its injection, are given in detail.

At the beginning of the work the material for injection was prepared as follows:

The normal glands were obtained as fresh as possible from necropsy cases and kept in normal salt solution, with a small amount of chloroform, in the ice-box until they were further prepared. No glands were used which stood longer than over night in such condition. They were then ground to a fine pulp in a food-chopper and then macerated with chemically pure sand in a mortar, after which the glands were extracted with from three to four times their volume of normal salt solution made faintly alkaline with sodium hydroxid (from 3 to 4 drops of 10 per cent. sodium hydroxid to 1 liter of sodium chlorid solution). Before the salt solution was added, all blood was strained off through gauze, so that only the solid part was used. The mixture was then shaken vigorously for about an hour, after which it was transferred to the refrigerator for from twelve to eighteen hours, a small amount of chloroform being added to keep down any possible contaminating bacterial growth. At the end of from twelve to eighteen hours the material was filtered through gauze and then fine filter-paper. The filtrate was weakly acidified with acetic acid and heated at 44 C. (111.2 F.) for ten minutes or longer, according to the time necessary to bring down the precipitate. This precipitate was washed repeatedly with normal salt solution, until the washings no longer gave the biuret reaction. It was then dissolved by rendering the precipitate faintly alkaline with 10 per cent. sodium hydroxid and filtered through heavy filter-paper. In every preparation made, this procedure was repeated to insure a perfectly pure product. It is needless to say that this was all done in as sterile a manner as possible. Cultures were made from the end-product, and if bacterial growth appeared, this was discarded. This is the method of Beebe.[1]

---

* From the Pathological Laboratory of St. Luke's Hospital.
* Read before the Chicago Pathological Society, April 13, 1914.

In each of the preparations the gross material was weighed and the solution measured, so that the equivalent of a certain amount of gross thyroid might be estimated by measuring out certain amounts for injection.

With this material the following animal inoculation experiments were carried out:

Belgian Hare 1.—Dec. 23, 1912: Injected intraperitoneally with the equivalent of 15 gm. human thyroid.

December 30: Injected with the equivalent of 20 gm. thyroid.

December 31: That morning the hare was found dead. The necropsy revealed no peritonitis or any gross pathologic changes. Cultures were sterile.

Hare 2.—Jan. 2, 1913: Injected intraperitoneally with the equivalent of 10 gm. thyroid.

January 8: Injected with equivalent of 15 gm. thyroid. The hare died some time during the night. The necropsy showed no gross pathologic changes, but the symptoms seemed to be rather anaphylactic in type. Cultures were sterile.

Hare 3.—Jan. 14, 1913: Injected intraperitoneally with the equivalent of 7 gm. thyroid.

January 19: Injected with the equivalent of 12 gm. thyroid. The hare died about four hours later from what appeared to be anaphylactic shock. There were no gross pathologic findings, and cultures were sterile.

Ram 1.—Dec. 23, 1912: Injected intraperitoneally with the equivalent of 85 gm. thyroid.

December 30: Injected with the equivalent of 100 gm. thyroid. On injection gas bubbles having a strong odor of hydrogen sulphid escaped through needle. The ram appeared well.

Jan. 7, 1913: Injected with the equivalent of 120 gm. thyroid. About five minutes after injection the ram had marked defecation and was very unsteady on its feet. In the afternoon it appeared to have recovered.

January 16: Injected with the equivalent of 90 gm. thyroid.

January 18: The ram died some time during the night. The heart's blood gave almost pure growth of staphylococcus. There was slight inflammation of the omentum at the point of injection. No peritonitis was seen. The left lung showed consolidation, and a purulent material could be squeezed out of the small bronchioles. The intestines were very much dilated. The thyroid gland was very small and of hard consistency. No other gross pathologic changes were found.

Ram 2.—Jan. 27, 1913: Ram injected intraperitoneally with the equivalent of 100 gm. thyroid.

February 1: Injected with the equivalent of 95 gm. thyroid.

February 8: Injected with the equivalent of 125 gm. thyroid.

February 13: Injected with the equivalent of 120 gm. thyroid. On the morning of Feb. 16, 1913, the ram was found dead. No necropsy was held, but during the course of the injections the animal showed almost typical signs and symptoms of hyperthyroidism.

Following these experiments a change was made in the immunization. The method of preparation was the same, but 1 gm. of thyroid to 100 c.c. of normal salt solution was used. This 1 per cent. solution was injected in smaller doses than in the previous experiments.

One hare and one ram were inoculated, the date and results being as follows:

Belgian Hare.—May 16, 1913: Injected intraperitoneally with 5 c.c. of this 1 per cent. solution.

May 22: Injected with 10 c.c. of 1 per cent. solution.

May 28: Died toxic death; cultures were sterile.

Ram.—May 17, 1913: Injected intraperitoneally with 10 c.c. of 1 per cent. solution.

May 22: Injected intraperitoneally with 20 c.c. of 1 per cent. solution.

June 2: Injected intraperitoneally with 40 c.c. of 1 per cent. solution.

June 9: Injected intraperitoneally with 45 c.c. of 1 per cent. solution.

June 20: Injected intraperitoneally with 75 c.c. of 1 per cent. solution.

July 14: Injected intraperitoneally with 65 c.c. of 1 per cent. solution.

July 3 the ram was bled and 600 c.c. of blood removed.

July 20 the ram was bled to death and about 4.5 liters of blood were obtained.

July 14 a healthy ram was bled to have normal blood for purposes of control.

The serum obtained from the immunized ram was studied for the presence of agglutinins. This is taken as an indication of the presence of specific antibodies and also determines their strength. We standardized ours according to the method of Beebe as follows:

Fresh human thyroid was ground very fine and extracted with normal salt solution. The mixture was then strained through gauze to remove the coarser particles and then centrifuged in a high-power machine. The upper layer of the sediment, together with a small amount of the supernatant liquid, was thoroughly shaken, a small amount of normal salt solution was added and the shaking repeated. This was placed in 1 c.c. amounts in small tubes. To each tube, 1 c.c. of various dilutions of the immune serum was added. For control, 1 c.c. of similarly diluted normal ram's serum was added to another set of tubes. The contact method was used and the serum floated on the emulsion. This method brings about the reaction more distinctly. In the dilutions of 1 : 2 and 1 : 10 the agglutination ring was observed within a few minutes, and in higher dilutions of 1 : 100 after standing for several hours.

The normal serum gave no reaction at all, and we were quite enthusiastic. Dr. Wells suggested that we make similar tests, using emulsions of other human viscera. In exactly the same manner described, emulsions were prepared from the kidney, liver and spleen and these all gave as marked and as prompt a reaction with the immune serum, as did the emulsion of the thyroid.

The method used by Beebe and followed by us does not, according to Wells, produce nucleoproteins, but rather salts of protein and nucleic acids. He says:

> It seems probable that in the living cell the nucleic acids must exist bound to protein molecules, but that these compounds are the same as those which are precipitated from either neutral or alkaline extracts of the cells or tissues, is highly doubtful, a fact universally recognized by physiological chemists. With an abundance of proteins of all sorts and conditions present in such extracts and in view of the easy dissociation of the compounds of nucleic acid and proteins, it is to be supposed that the nature and proportion of the protein which is thrown down with the nucleic acid will depend entirely on the conditions existing at the time. Variations in the concentration and character of the proteins, in the proportion of nucleic acid, of the concentration of salts and other solutes, of the degree of acidity and alkalinity of the solution, and perhaps even of the temperature, will all serve to cause variations in the composition of the precipitate which contains the nucleic acid.

---

[1] Beebe: Am. Jour. Pharm., 1911, lxxxiii, 56.

Pearce and Jackson, after a number of carefully conducted experiments, in 1906, could not confirm the work of Beebe. They did not find any evidence that injections of nucleoproteins produced a specific cytotoxic serum.

Taylor, in 1911, published his experiences with a serum produced according to the earlier methods of Beebe. He used thyroid glands removed by operation from exophthalmic goiter patients, and injected their nucleoproteins into hares. The serum did not show beneficial action in any of the cases in which it was used.

CONCLUSIONS

Nucleoproteins, so-called, of human thyroid glands do not act as specific antigens.

The antibodies produced are probably due to the small amount of protein contained in the injected material.

The action of the serum, so produced, is not specific for the thyroid gland alone, but has a similar action on other organs, especially the liver, kidney and spleen.

We wish to express our thanks to the authorities of St. Luke's Hospital for the privilege of conducting these experiments at their laboratory, and to acknowledge our indebtedness to Drs. Hektoen, Le Count, Wells, Davis and Moody for frequent advice and courtesies.

AN AID TO PROGNOSIS IN PULMONARY TUBERCULOSIS

A SIMPLE URINARY TEST: THE UROCHROMOGEN REACTION OF WEISZ

JEREMIAH METZGER, M.D.
AND
SAMUEL H. WATSON, M.D.
Medical Directors, Tucson-Arizona Sanatorium for Tuberculosis
TUCSON, ARIZ.

We think that all physicians who have had any considerable experience in the treatment of patients with pulmonary tuberculosis will agree that in many cases it is difficult to make an accurate prognosis. Will this patient recover? Will that patient succumb? These are questions that cannot always be answered correctly. Because of these facts, any test or procedure which will in the slightest degree assist in making more accurate prognoses, especially if simple and easily applied, demands careful attention. We have, therefore, felt justified in outlining our experience with Weisz' urochromogen reaction in the urine of patients sick with pulmonary tuberculosis.

For several years we have considered the presence of a diazo-reaction in the urine (if more than transient) as an unfavorable prognostic sign,[1] but unfortunately the actual practical value of the diazo-reaction is limited, for its absence is not necessarily a favorable prognostic sign, many cases with a hopeless prognosis failing to show it. We have often thought how valuable might be some test or reaction having the same significance as the diazo but more uniformity in its appearance in the urine, if it could be found. It was with considerable satisfaction, then, that a little more than two years ago we noted the publication of a paper by Lieutenant Heflebower,[2] pathologist to the United States Army Tuberculosis Sanatorium, Fort Bayard, N. Mex., describing just such a reaction and his experience with it. We at once determined to add this test to our routine urinary examinations. While two years is too short a time to establish definitely the full value of any test in such a chronic disease as tuberculosis, still, as our experience with it tends to confirm the views held by both Weisz,[3] its originator, and Heflebower, who, so far as our knowledge is concerned, first called attention to it in this country, we have been tempted to report our results, mainly in the hope that others may be induced to use it, so that after several years enough independent reports may be available, covering a sufficiently long period of time, to establish its value fully.

Weisz, after nearly six years of experimental work, found that urochromogen is the principal substance which causes the diazo-reaction, urochromogen itself being a low oxidation product of urochrome, the normal yellow coloring-matter of the urine. He found that one reason for the lack of uniformity in the appearance of the diazo-reaction is that urochromogen has an antecedent which does not react with the diazo-reagent. He furthermore found that a potassium permanganate solution, added to urine, demonstrated the presence of both urochromogen and its antecedent. It will thus be readily seen that this reaction would be expected to be more constant and uniform in its appearance than the diazo, and Weisz and Heflebower have both found this to be so. According to Weisz, urochromogen, being a low oxidation product of urochrome, occurs in the urine only when there is a condition of faulty oxidation. This condition of metabolism is present only when catabolism is affected by some toxin circulating in the blood, and such a condition is present in pulmonary tuberculosis, so he says, only when the focus in the lung is so active or extensive as to surcharge the blood with toxins or battle down the defensive forces of the body, which would otherwise neutralize the effect of these toxins.

As to the value of the test in actual practice, Weisz' personal views, as quoted by Heflebower, are the following:

1 Patients who at the beginning of a course of treatment do not show a disappearance of urochromogen from their urine have a hopeless prognosis.

2. The transient appearance of urochromogen can be found in acute exacerbations of the disease, and is to be regarded as a symptom of progression of the tuberculous process.

3. A distinction between continuous and transient, constant or occasional appearance of urochromogen should be made only as to the prospective duration of the disease.

4. Patients with transient excretion of urochromogen may, if external conditions are favorable, continue to live for several years, while the constant appearance of the reaction, especially when it is plainly becoming more intense, shows a rapid progress of the disease in the lungs and a hopeless prognosis.

Heflebower concludes that:

1. The frequency and constancy of the appearance of diazo and urochromogen reactions in the urines in cases of pulmonary tuberculosis constitute an index to the severity of the condition, a constant negative

---

[1] Provided always that certain drugs have not been administered for some time before the sample of urine is collected for examination.

[2] Heflebower, Roy C.: Am. Jour. Med. Sc., February, 1912, p. 221.

[3] Weisz, Moriz: München. med. Wchnschr., 1911, lviii, 1348.

result pointing to a case that is progressing favorably, while a constant positive result indicates a progressively downward case.

2. The urochromogen test occurs more frequently and is more constant than the diazo-reaction. It is, therefore, a better index to the condition of the patient than the diazo-reaction.

3. The intensity of both the diazo and urochromogen reactions is of great import as an index to the severity of the condition, especially as a method of determining the difference in prognosis in cases which show the reactions constantly.

Heflebower also says that "cases showing urochromogen more constantly are for the most part those cases that are having the greatest temperature elevations and loss of weight." This would be expected, for the majority of patients who are not doing well and who do not recover are of that type, but many times this type of case does not show a urochromogen reaction, and it is just here that it is of most value; for by its absence it shows that that particular patient, in spite of seeming and being seriously sick, has a resistance to the disease which the one showing urochromogen has not, and for the time being at least, a more hopeful prognosis may be made. On the other hand, patients not having great temperature elevation, loss of weight, or much lung involvement — patients who, in other words, do not seem to be very sick, and in whom one would ordinarily be tempted to make a favorable prognosis — occasionally show a persistent urochromogen, and in our experience, the great majority of these do not improve. The latter are the cases Weisz means when he says:

> There are some cases whose condition of the lungs is not such that you would be persuaded to give a bad prognosis and who through the presence of urochromogen in the urine first reveal the serious nature of their illness. Parallel with the development of the disease, you find an apparent increase in the excretion of urochromogen.

While we do not make any final conclusions in connection with this report from a prognostic point of view, on account of the reasons stated above, we cannot, on the other hand, help but believe from a study of our observations that the urochromogen reaction does bear a fairly constant relation to the clinical condition of a patient.

Of 113 cases included in this report, 5 were classified as incipient, 28 as moderately advanced and 80 as far advanced. Of the cases of incipient tuberlosis, the urochromogen reaction was negative in 100 per cent., and all of these patients have either recovered or are progressing to recovery. Of the 28 moderately advanced cases, the urochromogen reaction was positive in 32 per cent., and negative in 68 per cent. Of the 32 per cent. positive reactions, comprising 9 cases, 2 patients, or 22 per cent., showed a continuous positive urochromogen reaction and showed no clinical improvement while under observation. In 7 cases, or 78 per cent., the urochromogen reaction was changed from a positive to a negative during treatment, and this change from positive to negative was coincident with a clinical improvement. Of the 68 per cent. negative reactions, comprising 19 cases, 18 cases, or 95 per cent., showed a continuous negative reaction, and of these, 17 patients showed pronounced clinical improvement, and in 1 the condition remained stationary. In 1 case, or 5 per cent., the urochromogen reaction was changed from a negative to a positive, and this change was without any clinical change for the worse in the patient.

Of the 80 far-advanced cases, the urochromogen reaction was positive in 55 per cent. and negative in 45 per cent.; of the 55 per cent. positive reactions, comprising 44 cases, 34 cases, or 77 per cent., showed a continuous positive reaction, and of these, 28 patients became clinically worse and 6 showed clinical improvement. In 10 cases, or 23 per cent., the urochromogen reaction was changed from positive to negative during treatment; 7 of these patients showed coincident clinical improvement, while 3 became worse. Of the 45 per cent. negative reactions, comprising 36 cases, 28 patients, or 78 per cent., showed a continuous negative reaction, and of these, 20 patients showed clinical improvement and 8 became worse. In 8 cases, or 22 per cent., the urochromogen reaction was changed from a negative to a positive, and in 7 of these, the patients became coincidentally worse, while 1 showed improvement.

Heflebower used a control-tube of urine in all of his tests; and because we found, as he says, that "it enables one to distinguish very slight changes of color," we have done the same, performing the test as follows:

Into each of two small test-tubes is put 1 c.c. of urine, and 2 c.c. of distilled water are added; now, to one tube which is to be tested for urochromogen, 3 drops of 1 : 1,000 solution of potassium permanganate are added, the tube is shaken thoroughly and compared with the control tube. The appearance of the faintest yellow color shows the presence of urochromogen and is easily detected by comparing with the control-tube, to which no potassium permanganate is added. The test is read positive, however, only when the solution stays clear.

Our experience with the urochromogen reaction covers over two years in 113 patients. Some individual patients were observed as long a time as two years, the presence or absence of urochromogen being determined every month, the average length of time the entire number of patients were under constant observation being about four months for each patient.

SUMMARY OF TESTS

Type of Case	Number of Cases	Urochromogen Reaction Positive Per Cent.	Negative Per Cent.
Incipient	5	0	100
Moderately advanced	28	32	68
Far advanced	80	55	45

In the light of our experience with the urochromogen reaction, in these patients, it appears to us that the following statements seem at the present time permissible:

1. The presence of a urochromogen reaction in the urine of a patient sick with pulmonary tuberculosis is for the time being of unfavorable prognostic import.

2. The persistent presence of a urochromogen reaction in the urine, in spite of proper treatment, probably means a hopeless prognosis.

3. Its absence is generally, though not invariably (regardless of how sick the patient seems), of good prognostic import.

4. Its prompt and continued disappearance soon after treatment is instituted, in a patient who showed it before treatment, so far as our experience goes, is a favorable prognostic sign; but it will take several

years' observation of these particular patients to determine this point conclusively.

5. Finally, it is not an invariable guide to prognosis, but in the majority of cases is of much value, and as all prognoses must be good, bad or doubtful, it will, if judicially used, help materially to reduce the number in the doubtful class.

JUVENILE PARESIS TREATED BY THE INTRASPINAL INJECTION OF SALVARSANIZED SERUM *

REPORT OF A CASE

C. EUGENE RIGGS, A.M., M.D.
Professor Emeritus of Nervous and Mental Diseases, University of Minnesota Medical School
ST. PAUL

Thirty-seven years ago Dr. Clouston reported the first case of juvenile paresis under the name of developmental general paralysis. Until that time paresis was believed to be essentially a disease of the adult. I have found in medical literature to date records of 228 cases of this disease, and there are other references to which I have been unable to gain access. Clouston made it clear that the symptoms presented by his patient, a boy of 16, differed in no way clinically or pathologically from those of the generally recognized type. The investigations of Noguchi and his co-workers have clearly established the truth of this contention. The real significance of the term "juvenile" is that of *time incidence;* the fact that in one case we are dealing with a congenital and in another with an acquired syphilis is a matter of no moment. In either instance the symptoms are the direct results of the activities of the *Spirochaeta pallida* on the brain cortex. One fact is clearly apparent, that any young congenital syphilitic is potentially a juvenile paretic, and Abraham states that all children of syphilitic parents, giving a positive Wassermann, whether or not they show any evidence of congenital syphilis, should be treated as carefully as if they were adults with definite symptoms of the disease.

The clinical syndrome of the juvenile form varies with the time of onset. Delusions of a sexual nature and grandiose ideas of wealth, strength and ambition do not occur until after puberty. About one-half of the cases develop after adolescence, although the disease may occur in the very young, showing itself by mental retardation or feeble-mindedness.

According to Fennell, 5 per cent. of imbecile children are congenital general paretics. Optic atrophy is an early symptom. Juvenile paresis develops about equally in the two sexes, perhaps slightly more frequently in the female. The cases usually fall under the demented type, but one of Mott's patients and five of Kleinberger's showed grandiose ideas.

The clinical symptoms are so variable and uncertain, however, that often it is only by the serobiologic findings that one can arrive at a diagnosis.

The report of the following case is of interest not because of the rarity of the disease, for it is comparatively frequent, or of anything unusual or distinctive in the clinical syndrome, but rather because of the use of salvarsanized serum intraspinally in this patient.

C., a boy aged 8½ years, was the second child in a family of five, the first having been still-born. The father contracted lues at 17, and according to his statement infected his wife. The blood-serum in his case gave a positive reaction while his wife, on the other hand, presented a negative Wassermann in both blood-serum and spinal fluid. The pressure of the latter was increased. Both the Noguchi and the Nonne tests were negative, as was the Lange colloidal gold reaction. There were twenty-six lymphocytes to the cubic millimeter. Physicians who had seen this woman at the time of her supposed infection were of the opinion that it was luetic. The blood-serum in two younger children aged 5½ years and 5 months, respectively, reacted negatively, while a third, 2½ years of age, gave a positive Wassermann in the blood-serum. The entire family, aside from the patient, gave no clinical evidence of syphilitic infection of the central nervous system, nor were there any symptoms of congenital syphilis in the other children.

Nothing abnormal was observed in C. until the fourth year, when it was noticed that his memory was failing and his face had a vacuous expression. He was sent to school in his seventh year but was unable to learn the simplest things. He was severely punished by his teacher because of his being so unruly and difficult to control. At this time also his walking became difficult and he used his hands in a clumsy manner. The father stated that the deterioration, both mental and physical, had been very rapid during the past year. When I saw him first he acted in a silly manner; he could not feed himself and needed constant oversight, and he talked like a young child.

Examination showed Argyll Robertson pupils, exaggerated knee-jerks, with ankle-clonus and Babinski in both feet. There was marked Rombergism. There was no nystagmus or epileptiform seizures; the background of the eye was normal. There were no signs of congenital syphilis. Serobiologic findings were increased pressure in the spinal fluid and positive Wassermann in both blood-serum and spinal fluid, the latter in all dilutions down to 0.05 c.c. Lange's colloidal gold test gave the characteristic curve of paresis. Noguchi positive; Fehling's normal; lymphocytosis seventy-two to a cubic millimeter.

Before the introduction by Swift and Ellis of the intraspinal method for the injection of salvarsanized serum, few physicians considered juvenile paresis as worthy of treatment because of its being so utterly hopeless. In 1910 Abraham treated a case with intramuscular injections of salvarsan without benefit. In April, 1913, Cotton used salvarsanized serum intraspinally in a case of juvenile paralysis with decided benefit clinically and serobiologically. "It is fair to assume," says Swift, "that arsenic or other drugs introduced into the spinal canal by means of lumbar puncture reach all points of the cerebrospinal system (at least the larger cavities) which are bathed by the cerebrospinal fluid."

The experiments at the Rockefeller Institute with the direct injection of neosalvarsan into the spinal canal, as well as the unfortunate experience at Los Angeles, should be sufficient warning to prevent its further use in this manner, notwithstanding the brilliant work being done by Ravaut and Marinesco with the *in vitro* method. Whatever the anatomic facts may be, the superiority, clinically and serobiologically, of the intraspinal use of salvarsanized serum over all other methods, is beyond cavil or question.

C. has received eight intravenous injections, each of 0.25 gm. of salvarsan followed the next day by an intraspinal injection of 30 c.c. of 40 per cent. solution of salvarsanized serum. The serobiologic reduction has been very slight. The pressure of the spinal fluid is normal; lymphocytes three to the cubic millimeter. Blood-serum is less positive, spinal fluid unchanged. The paretic curve of Lange's colloidal gold test rem[illegible]

---

* Read before the American Neurological Association, Albany, N. Y., May 8, 1914.

C[illegible] has been more noticeable. C. can now feed himself; his silly actions and vacuous expression have disappeared; he is much brighter mentally, requires less oversight, observes things much more than formerly, shows some interest in games and talks much more normally. His gait is greatly improved. His parents and all others who have come in contact with him notice the difference; yet notwithstanding all this apparent improvement he has just had his first epileptiform seizure.

It will be observed that Lange's colloidal gold test, which I believe has a real corroborative value, gave the curve of paresis in this patient. In every case of paresis or taboparesis in which we have employed it, it has given the typical reaction of this disease.

In two cases of multiple sclerosis Kaplan observed that one gave the curve of paresis and the other reacted negatively; one case of multiple sclerosis which we examined with this test also gave the latter reaction. A case of tabes without any mental symptoms in a professional man of unusual mentality gave the curve of paresis, while two other tabetics gave that of tabes. According to Jelliffe, if the four reactions are positive, small amounts of spinal fluid being used (from 0.05 to 0.2 c.c.), the diagnosis is almost certainly paresis. In one of our cases in which there were no mental symptoms whatever, nothing except an Argyll Robertson pupil and a left hemiplegia, due to a luetic endarteritis, the serobiologic findings being as above, the Lange test gave the typical paretic curve. Does this mean that in both these cases with no paretic indications paresis will ultimately develop? In several cases in which there have been serobiologic reductions there have been no changes in the paretic curves. Much further observation will be necessary to determine the real significance of this reaction.

In three cases of paresis, in all of which six or more injections of salvarsanized serum have been given, there have occurred two remissions, one of which lasted about two months, while the other one still persists. The third case, belonging to the demented type, has shown no improvement. In the cases which remitted there were very decided serobiologic reductions; in the unimproved patient these were very slight. Our experience has been that clinical betterment and serobiologic reductions go hand in hand. Nothing can be hoped for from the intraspinal method in advanced paresis, yet as Cotton states, there are no contra-indications to its use.

The reaction following the intraspinal injection of salvarsanized serum is as a rule negligible. The temperature seldom reaches 100; usually it is about 99, and the increase lasts from twenty-four to forty-eight hours. Formerly we observed higher temperatures, but with an improved technic they have disappeared. There is a marked increase in the lightning pains of tabetics for twenty-four or forty-eight hours after injection, but aside from the period of the injection these appear to be greatly benefited. The relief of dribbling and retained urine is sometimes truly remarkable.

In only one instance have we observed any untoward symptoms. This was a case of acute luetic meningomyelitis developing on a tabetic base. Twenty-four hours after the fourth intraspinal injection (there was practically no reaction following the three preceding ones), the patient became restless, anxious, and developed slight muscular twitchings. Temperature and pulse were normal. Within four hours the former had risen to 104.2, and the pulse was 100. The patient was absolutely unconscious and remained so for three days. The neck and back were rigid, the Kernig sign was marked and there was every indication of a suppurative meningitis, but the spinal fluid was sterile. The patient gradually improved and is now much better than before he received the injection. Without doubt this is an instance of aseptic chemical meningitis due to the intraspinal use of salvarsanized serum. Swift and Ellis call attention to the fact that the intraspinal injection of salvarsanized monkey-serum in the normal monkey may cause a large increase of cells in the spinal fluid, chiefly polymorphonuclears. In our more than seventy-five injections we have never seen any increase of the polymorphonuclear leukocytes following an injection of salvarsanized serum except in the case above mentioned and in one paretic, when a lumbar puncture caused an intraspinal hemorrhage which cleared up in about four weeks.

There can be little doubt that an aseptic, chemical meningitis presenting all the manifestations, clinical and pathologic, of an acute suppurative meningitis without the infecting organism, may arise from the introduction into the spinal canal of a foreign serum (Sicard, Sophian, Sladen, Brem). My case demonstrates that the same alarming symptoms may follow the injection of the salvarsanized serum.

Endicott Arcade.

Accidental Electrocution by a Weak Current.—Mr. S. was employed in handling pickled fish on a fish wharf. The immense fish-storage shed in which he worked was lighted by electricity in sections, the system being a part of that which operated the plant of the electric light company on the next wharf, the transformer serving for both lighting systems. The small switch-room was in the corner of the lower floor of an adjacent wooden building. At about 11 a. m., Oct. 2, 1913, a dark, misty day with occasional rain, S. desired to work in another part of the shed and therefore went over to the switch-room to adjust the switches. As those who used the switch were generally workers in pickle, salt was present on the damp floor and woodwork. S. did not at the time have rubber boots on. He touched the switch and then leaned against the wall in a crouching position, which was observed by another workman who seized him and threw him out of the switch-room on the asphalt walk, receiving as he did so a violent electric shock. When I arrived a few minutes later, I found no pulsation at the wrist and no heartbeat, but efforts at resuscitation were continued for about one hour when the patient was pronounced dead. The necropsy, made by Medical Examiner S. F. Quimby and witnessed by several physicians, was delayed by legal formalities; it revealed no previously existing pathologic conditions which could have produced death at that time. No method of preservation had been used and it was observed that post-mortem rigidity was less than normal and the skin color more life-like than is usual. The possibility of crossed wire having been eliminated and a test having shown that the voltage of the current which passed through the body of S. did not exceed 111, it was decided that he had been electrocuted by a current not exceeding this strength, which passed through him while his clothes and body were damp from being in pickle and the switch-room also damp with pickle.—C. H. Morrow, M.D., Gloucester, Mass.

New Instruments and Suggestions

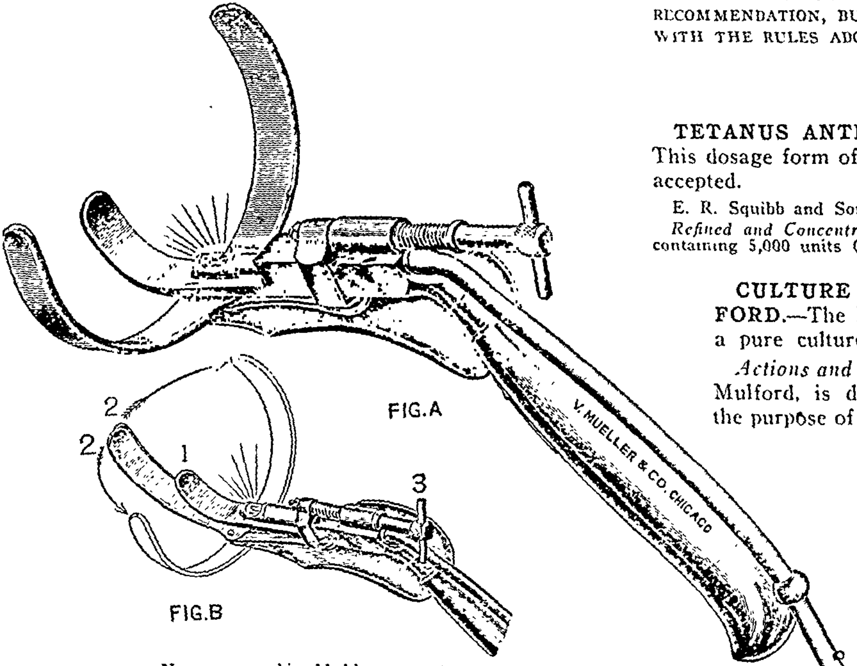
A NEW SUPRAPUBIC BLADDER RETRACTOR

B. C. Corbus, M.D., Chicago
Instructor in Genito-Urinary Diseases, Rush Medical College.

For descriptive purposes, this instrument can be divided into three parts, (1) the shaft, (2) retracting blades, and (3) the light-carrier. The shaft is again subdivided into (1) the vertical handle, and (2) the horizontal main section.

The vertical section is merely a rounded shaft, shaped so as to be easily held in the hand, while retracting. At the lower end is a hole to admit the peg of the light-staff, thus preventing any free play of the light apparatus after its adjustment.

The main or horizontal section of the shaft with its connections serves as a posterior abdominal and bladder-wall retractor, admits the light-staff, serves as a post for the sliding square connecting the screw (3) and the small arms of the bladder blades and carries a pivot-peg for the attachment of the main retracting arms. Through its center is the canal admitting the light-staff. On the upper surface is the screw (3) attached to the sliding square, and so threaded that after the insertion of the closed blades, as seen in Figure B, four complete revolutions open the blades widely. Protruding from the under aspect of the main section, immediately behind the light, is placed the pivot-peg. At the opposite end a strip (not shown in the illustration) is attached, serving to fix firmly the wide posterior abdominal retracting blade. The latter, by the adjustment of the bladder blades to the pivot-peg, is at this point also anchored.



New suprapubic bladder retractor.

The true bladder-blades are of two sizes, small and large, according to the size and contractility of the bladder. Each set of blades consists essentially of two separate arms with rounded edges to avoid injury to the bladder mucosa on opening, and are jointed separately to the pivot-peg. The blades are also connected by two small arms to the sliding square, whose upward or downward passage controls the opening or closing of the retracting blades. The connections are all slip-on joints, so as to permit expeditious adjustments of the blades in changing, the whole making a unique combination of abdominal and bladder-wall retractor.

The lighting apparatus completes the instrument and is rather unique in the brightness of its cold tungsten bulb, the ease of its admission and removal for cleansing in case of obscuring the lamp by blood, and finally the surety of good electrical contact at the end of the staff by the spring-bayonet contact points.

The instrument on introduction through the suprapubic incision occupies no more space than the index-finger.

As the bladder is capable of being distended to a greater degree in the transverse diameter, this instrument is particularly advantageous in examining the internal urethral orifice, both before and after prostatectomy, in suturing over the cut surfaces of the mucosa after prostatic enucleation, in excising tumors and all operations on the ureter that are made intravesically.

32 North State Street.

New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

TETANUS ANTITOXIN.—(See N. N. R., 1914, p. 243). This dosage form of an accepted proprietary article has been accepted.

E. R. Squibb and Sons, New York.

Refined and Concentrated Tetanus Antitoxin.—Marketed in packages containing 5,000 units (curative dose) put up in syringe containers.

CULTURE OF BULGARIAN BACILLUS, MULFORD.—The Mulford culture of Bulgarian bacillus is a pure culture in tubes of the *Bacillus bulgaricus.*

Actions and Uses.—The culture of Bulgarian bacillus, Mulford, is designed for internal administration for the purpose of establishing lactic-acid-producing bacilli in the intestines. It is claimed that these bacilli are of value in diseases and toxic conditions due to putrefaction in the intestines and are of service in arresting putrefaction in wounds, abscesses and in the various body cavities. Thus it is said to be beneficial in chronic suppurative processes of the nasal passages, and the accessory sinuses, the middle ear, the endometrium and of the vagina.

Dosage.—One tube of the culture in 3 tablespoonfuls of water containing a lump of sugar or taken in a half or full glass of milk. This dose should be repeated morning and evening after meals. The tubes must be kept in a cold place and should not be used after the date stamped on the package.

Manufactured by H. K. Mulford Company, Philadelphia. No U. S. patent or trademark.

LACTOBACILLINE TABLETS.—Tablets containing a pure culture of the *Bacillus bulgaricus.*

Actions and Uses.—The bacilli contained in lactobacilline tablets give rise to the production of considerable quantities of lactic acid, which tends to restrain the growth of putrefactive organisms. They are said to be useful in diseases of the alimentary tract and in such general diseases as are believed to depend on putrefaction in the intestines.

Dosage.—One or two tablets after meals. Lactobacilline tablets are marketed in boxes containing eight tubes of six tablets each, with an expiring date stamped on the label. They should be kept in a cold place.

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

Lactobacilline tablets are prepared from the pure cultures of the *B. bulgaricus* which is mixed with lactose and a suitable non-potent mechanical vehicle, slowly dried and compressed. Each tablet contains an abundance of viable *B. bulgaricus* in pure culture and should coagulate 1 liter of sterilized milk in from thirty-six to forty-eight hours when incubated at from 40° to 44° C.

LACTOBACILLINE LIQUIDE, CULTURE A.—Lactobacilline liquide, Culture A, is a pure culture in tubes of the *Bacillus bulgaricus* grown in a neutralized sugar bouillon, each tube containing from 5 to 6 Cc.

Actions and Uses.—See Lactobacilline Tablets.

Dosage.—One or two tubes of the culture are taken twice a day in a small quantity of sweetened water before meals. The tubes should be kept in a cold place, and should not be used after the date stamped on the package.

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

One Cc. should coagulate 1 liter of sterile milk in from twelve to twenty-four hours when incubated at from 37.5° to 40° C.

The object of this liquid culture is to secure the maximum quantity of virile and active organisms in a nutrient medium for direct administration.

LACTOBACILLINE LIQUIDE, CULTURE D.—Lactobacilline liquide, Culture D, is a pure culture in tubes of the *Bacillus bulgaricus* grown in a neutralized bouillon.

Actions and Uses.—See Lactobacilline Tablets.

Dosage.—One or two tubes of the culture are taken four times a day in a small quantity of water. The tubes should be kept in a cold place and should not be used after the date stamped on the package.

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

Lactobacilline Liquide, Culture D, Small.—Tubes containing 5 Cc. of pure cultures of the *Bacillus bulgaricus* grown in a neutralized bouillon.

Lactobacilline Liquide, Culture D, Large.—Tubes containing 16 Cc. of pure cultures of the *Bacillus bulgaricus* grown in a neutralized bouillon.

This culture contains a minimum amount of sugar and a heavy growth of virile and active organisms. One Cc. should coagulate 1 liter of sterile milk in from twelve to twenty-four hours when incubated at from 37.5° to 40° C.

LACTOBACILLINE LIQUIDE, INFANT'S CULTURE.—Lactobacilline liquide, infant's culture is a pure culture in tubes of the *Bacillus bulgaricus* in a whey medium.

Actions and Uses.—This preparation is employed in the treatment of diarrhea or dysentery in nursing infants or young children.

Dosage.—One or two tubes a day, administered in an equal quantity of sterile water.

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

One Cc. of this culture should coagulate 1 liter of sterilized milk in from twelve to twenty-four hours when incubated at from 37.5° to 44° C.

LACTOBACILLINE GLYCOGENE TABLETS.—Tablets containing pure cultures of the *Bacillus bulgaricus* and the *Glycobacter peptolyticus.*

Actions and Uses.—The *Glycobacter peptolyticus* transforms into sugar the amylaceous substances in the diet, thereby furnishing a pabulum for the *B. bulgaricus,* which in turn transforms the sugar into lactic acid. These tablets are designed as a prophylactic against intestinal diseases, as well as a remedial agent in the treatment of ailments due to intestinal putrefactions, auto-intoxications, etc.

Dosage.—One or two tablets two hours after each meal.

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

Lactobacilline glycogene tablets are prepared from the pure cultures of the *B. bulgaricus* and the *Glycobacter peptolyticus* which are mixed with lactose and a suitable non-potent mechanical vehicle, slowly dried and compressed. Each tablet contains an abundance of viable bacilli and of glycobacter spores. Each tablet should coagulate 1 liter of sterilized milk in forty-eight hours when incubated at from 40° to 44° C. The characteristic film of the *Glycobacter peptolyticus* should be produced on nutrient bouillon in from twenty-four to thirty-six hours.

LACTOBACILLINE GLYCOGÈNE LIQUIDE.—Lactobacilline glycogene liquide is a pure culture in tubes of the *Bacillus bulgaricus* and the *Glycobacter peptolyticus.*

Actions and Uses.—See Lactobacilline Glycogene Tablets.

Dosage.—One tube in a wineglassful of water two hours after each meal. The tubes should be kept in a cold place and should not be used after the date stamped on the package

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

Lactobacilline Glycogene Liquide, Small.—Tubes containing 5 Cc. of pure cultures of the *Bacillus bulgaricus* and the *Glycobacter peptolyticus.*

Lactobacilline Glycogene Liquide, Large.—Tubes containing 16 Cc. of pure cultures of the *Bacillus bulgaricus* and the *Glycobacter peptolyticus.*

One Cc. should coagulate 1 liter of sterile milk in twenty-four hours when incubated at from 37.5° to 40° C., and should produce the typical film of the *Glycobacter peptolyticus* when grown on nutrient bouillon.

LACTOBACILLINE MILK TABLETS.—Tablets containing pure cultures of the *Bacillus bulgaricus* and *Bacillus paralacticus.*

Actions and Uses.—Lactobacilline milk tablets are used in the preparation of scientifically soured milk which serves as a means of administration of the *B. bulgaricus* and also possesses a nutritive value. It is used as a palatable nourishing drink, and in cases of intestinal indigestion and auto-intoxication.

Dosage.—One tablet should be placed in 1 liter (quart) of sterilized milk and incubated for twenty-four hours at 40° C.

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

Lactobacilline milk tablets are prepared from pure cultures of *B. bulgaricus* and *B. paralacticus* which are mixed with lactose and a suitable non-potent vehicle, slowly dried and compressed.

LACTOBACILLINE SUSPENSION.—Lactobacilline suspension is a pure culture in tubes of the *Bacillus bulgaricus* grown in a neutralized bouillon medium.

Actions and Uses.—This culture tends to inhibit the growth of deodorant, putrefactive and pathogenic organisms. It acts as an antiseptic and has been found beneficial in chronic suppurative conditions of the nasal passages, antrum, middle ear, in chronic abscesses, and in puerperal putrefactive processes of the endometrium and vagina.

Dosage.—The parts to be treated should be thoroughly cleansed with sterile water or a warm saline solution. The amount of culture to be applied depends on the extent and condition of the involved area, one or several tubes being necessary. The culture should be kept in a cold place, and should not be used after the date stamped on the package.

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

Lactobacilline Suspension.—Tubes containing 5 Cc. of pure cultures of the *Bacillus bulgaricus.*

Lactobacilline Suspension Surgical.—Tubes containing 20 Cc. of pure cultures of the *Bacillus bulgaricus.*

One Cc. of this culture should coagulate 1 liter of sterilized milk in from twelve to twenty-four hours when incubated at from 37.5° to 44° C.

LACTOBACILLINE MILK FERMENT.—Lactobacilline milk ferment is a pure culture in tubes of the *Bacillus bulgaricus* and *Bacillus paralacticus.*

Actions and Uses.—See Lactobacilline Milk Tablets.

Dosage.—One tube should be placed in a liter (quart) of sterilized milk and incubated for twenty-four hours at 40° C.

Manufactured by the Ferment Company, New York (The Franco-American Ferment Company, New York).

The organisms in this ferment are grown in a neutral sugar bouillon.

Typhoid Death-Rate and the Army.—The death-rate from typhoid fever per hundred thousand population in the registration area of the United States during the year 1912 (the last report available) was 16.5. The absence of a single death from typhoid in the nearly 100,000 officers and men of the Army who were protected by vaccination contrasts favorably with the 16.5 deaths per an equal number of the general population.—C. THE CONSTANCY OF ENDOGENOUS URIC-ACID EXCRETION

Among those who helped to overthrow the older notion that the urea and uric acid excreted in the urine have a common origin was the Bohemian physiologist, Professor Mares of Prague. As early as 1887[1] he formulated the hypothesis that uric acid is the product of the activity of cell protoplasm, whereas urea arises directly from the disintegration of proteins ingested as food. In the divorce of these two nitrogenous substances, urea and uric acid, which were long believed to have a direct genetic interrelationship, uric acid was accordingly made a derivative of that chemical process which forms the basis of cellular activity. The quantity of urea formed in a given time was clearly seen to depend above all on the amount of nitrogenous matter absorbed. When the possible relation of nucleoproteins and purins to uric acid began to be appreciated, Mares insisted that not only the nucleoproteins of the leukocytes (as had been previously maintained), but likewise those of any body-cells may give rise to uric acid.

To-day it is believed that both food-purins and tissue-purins and their precursors can give rise to the excretion of uric acid in man; and the physiologist distinguishes accordingly between the uric acid of endogenous and that of exogenous origin. The idea that the former can be derived in the human body by direct synthetic processes is not commonly accepted. It was Mares in particular who early advanced the conclusion that although the urea output of an individual on a purin-free diet may vary within very wide limits, the excretion of uric acid under these conditions approaches a constant which is fixed for the individual. So long as the view was sustained that uric acid is both formed and destroyed in the organism of man[2] it was not easy to understand how the remarkable fixity of the endogenous quota of uric acid could be maintained. For this reason, in part, the work of Mares was neglected and ceased to attract much recognition. Now that uric acid appears to be a true end-product of human purin metabolism[3] rather than an intermediate stage, the fixed character of the amount excreted when no purins are found in the diet may be viewed in a new light. Constancy in output can thus be interpreted as the expression of some definite function in the body, such as the routine activity of tissue-cells. It does not apply to those found in the muscles; for vigorous exercise does not markedly alter the endogenous output of uric acid. The secretory glands have been suggested as a more probable source of the latter.

If further evidence is needed to emphasize the often observed constancy in the quantity of endogenous uric acid eliminated by one person—a feature substantiated by many investigators in different parts of the world—it may be found in the latest contribution from Mares' laboratory. His assistant, Dr. Faustka,[4] has reinvestigated quantitatively the output of uric acid in some of Mares' earlier subjects, under the original conditions of diet—in one case after an interval of twenty-five years, the age of the subject at the second trial being 70. The variations in the output at the two periods of life were not more than a few milligrams. In 1886 the output was 8.11 mg. per kilogram of body weight in twenty-four hours, as compared with the figure 8.2 mg. for 1911. Other comparable cases have enforced a similar lesson, namely, that the quantity of uric acid excreted by the adult human organism in definite periods under fixed conditions is a physiologic constant.

It must not be assumed, however, that no importance attaches to an estimation of uric acid in the urine unless the endogenous constant is known. The dietary or exogenous sources of this urinary component are so varied and large in comparison with the quota furnished by the body itself, independent of the food intake, that the total daily output, under the usual conditions of feeding, is not significantly modified by incidental variations in the endogenous output. The essential importance of a study of the latter feature lies in obtaining one more constant, like endogenous creatinin, from which to estimate variations incidental to disease when suitable conditions arise.

SANITATION ON THE ISTHMUS OF PANAMA AND ON THE RAND

The report by Surgeon-General Gorgas[1] on the health of the mine laborers of the Rand which appears in this issue contains data and conclusions of the highest importance. The excessive death-rate from pneumonia among the imported or "recruited" native laborers is the central theme of the report, and Gorgas' valuable and unique Panama experience has been freely drawn on for comparison. It seems that for some time the pneumonia-rate on the Rand has been very high, ranging in 1912, for example, from 26.3 in the 21,000 tropical natives to 8 in the 199,000 non-tropical. Apart from the differences associated with race or origin, the suggestive fact is noted that the newly arrived native is by far the greatest sufferer from pneumonia. In 1912, out of 2,031 deaths from pneumonia among the Rand laborers, 1,199 were deaths of men who had been at the mines less than six months. The difference between the tropical and non-tropical natives may be at bottom of the same character since, according to Gorgas, "in general, the tropical is the non-civilized native who has had little contact with the white man's diseases, and the non-tropical, the native who has had more or less contact with civilization and the white man's diseases."

[1] Gorgas, W. C.: Recommendation as to Sanitation Concerning Employees of the Mines on the Rand Made to the Transvaal Chamber of Mines, p. 1855, this issue.

Taking this fact, which seems to be the only significant epidemiologic fact shown by the Rand statistics, as a starting point, Gorgas proceeds with a masterly analysis of the pneumonia situation as observed on the Isthmus of Panama. In the construction of the Panama Canal the conditions with regard to pneumonia were at the outset very similar to those found on the Rand. In 1906 the pneumonia death-rate among the negroes brought from the West Indies to the Canal Zone was 18.74 per thousand. With the aim of reducing this very high rate a careful study was made of a number of factors that might influence pneumonia. Altitude, ventilation and the effect of sleeping in wet clothes were in turn examined as possible predisposing causes, but in each instance with negative results. "The only difference in susceptibility was shown to be governed by the length of time that the laborer had been on the Isthmus." Pneumonia was four and one-half times as frequent among the men who had been on the Isthmus less than three months as among the men who had been on the Isthmus more than three months. In the Panama Canal Zone, however, the pneumonia-rate did not remain high. The pneumonia death-rate figures are: 1906, 18.74; 1907, 10.61; 1908, 2.60; 1909, 1.60; 1910, 1.66; 1911, 2.24; 1912, 1.30. Now the significant fact is that the sudden and remarkable drop after 1907 was coincident with a radical change in the manner of living. In 1907 the negro laborers were allowed to scatter out along the line of the Canal to "build each man his hut, with a small cultivable piece of land, and bring over his family." It is evident that under such conditions the opportunities for the transfer of pneumococci from carriers to non-immunes are much less favorable than under the barrack system. Gorgas definitely attributes the sudden and permanent drop in pneumonia on the Isthmus to the scattering of the negroes in independent dwellings.

Applying these facts to the Rand situation, the conclusion is drawn that the high pneumonia-rate on the Rand is due to the same factor of barrack overcrowding which was apparently responsible for the initial high pneumonia-rate on the Isthmus of Panama. In accordance with the Panama experience the recommendation is made that so far as possible the negro laborers be allowed to bring in their families and live with them in individual buildings. Where this is not possible much roomier native quarters should be provided. The present allowance (about 14 feet of floor-space!) is much too limited.

Gorgas' conviction that under the conditions described pneumonia is a disease spread largely by contact does not seem likely to pass unchallenged, to judge from the opinion recently expressed by Maynard,[2] who deals with the same body of Rand data reviewed by Gorgas. Maynard declares that "a study of these figures shows definitely that if infections from case to case play any part in determining the prevalence of this disease among 'tropical natives,' it can be, at most, but a very small one." Nevertheless, in view of the striking course of events at Panama, it is hard to see a way of escape from the conclusions reached in Gorgas' investigation.

Gorgas' article is full of details of an unusually interesting character. In Gorgas' opinion, vaccination against pneumonia is worth considering as a protective measure. In 1912 at the Premier Mine, 17,500 inoculated had a pneumonia death-rate of 6.89, and 6,700 uninoculated a death-rate of 17.72.

Those who believe that housing is a matter of real sanitary importance[3] will find support for their views in Gorgas' opinion as to the influence of the crowded quarters on the Rand. "The general objection to such crowding is that it causes the respired air to become vitiated. My great objection to such crowding is that it forces the occupants into close personal contact, and therefore largely increases the spread of any infectious disease."

The advocates of the restriction of liquor-selling will find comfort in Gorgas' views as to the value of even localized prohibition. "Alcohol for the natives, I believe, is an unmitigated evil. It is in no way necessary for his health; in fact it is always hurtful. . . . The two Panama towns of Colon and Panama, at the northern and southern end of the Canal, are not under the jurisdiction of the commission as far as regards liquor-selling. There is no restriction on an employee going to these towns and getting liquor as he wishes and bringing it out into the Zone to his own

THE CONSTANCY OF ENDOGENOUS URIC-ACID EXCRETION

Among those who helped to overthrow the older notion that the urea and uric acid excreted in the urine have a common origin was the Bohemian physiologist, Professor Mares of Prague. As early as 1887[1] he formulated the hypothesis that uric acid is the product of the activity of cell protoplasm, whereas urea arises directly from the disintegration of proteins ingested as food. In the divorce of these two nitrogenous substances, urea and uric acid, which were long believed to have a direct genetic interrelationship, uric acid was accordingly made a derivative of that chemical process which forms the basis of cellular activity. The quantity of urea formed in a given time was clearly seen to depend above all on the amount of nitrogenous matter absorbed. When the possible relation of nucleoproteins and purins to uric acid began to be appreciated, Mares insisted that not only the nucleoproteins of the leukocytes (as had been previously maintained), but likewise those of any body-cells may give rise to uric acid.

To-day it is believed that both food-purins and tissue-purins and their precursors can give rise to the excretion of uric acid in man; and the physiologist distinguishes accordingly between the uric acid of endogenous and that of exogenous origin. The idea that the former can be derived in the human body by direct synthetic processes is not commonly accepted. It was Mares in particular who early advanced the conclusion that although the urea output of an individual on a purin-free diet may vary within very wide limits, the excretion of uric acid under these conditions approaches a constant which is fixed for the individual. So long as the view was sustained that uric acid is both formed and destroyed in the organism of man[2] it was not easy to understand how the remarkable fixity of the endogenous quota of uric acid could be maintained. For this reason, in part, the work of Mares was neglected and ceased to attract much recognition. Now that uric acid appears to be a true end-product of human purin metabolism[3] rather than an intermediate stage, the fixed character of the amount excreted when no purins are found in the diet may be viewed in a new light. Constancy in output can thus be interpreted as the expression of some definite function in the body, such as the routine activity of tissue-cells. It does not apply to those found in the muscles; for vigorous exercise does not markedly alter the endogenous output of uric acid. The secretory glands have been suggested as a more probable source of the latter.

If further evidence is needed to emphasize the often observed constancy in the quantity of endogenous uric acid eliminated by one person—a feature substantiated by many investigators in different parts of the world—it may be found in the latest contribution from Mares' laboratory. His assistant, Dr. Faustka,[4] has reinvestigated quantitatively the output of uric acid in some of Mares' earlier subjects, under the original conditions of diet—in one case after an interval of twenty-five years, the age of the subject at the second trial being 70. The variations in the output at the two periods of life were not more than a few milligrams. In 1886 the output was 8.11 mg. per kilogram of body weight in twenty-four hours, as compared with the figure 8.2 mg. for 1911. Other comparable cases have enforced a similar lesson, namely, that the quantity of uric acid excreted by the adult human organism in definite periods under fixed conditions is a physiologic constant.

It must not be assumed, however, that no importance attaches to an estimation of uric acid in the urine unless the endogenous constant is known. The dietary or exogenous sources of this urinary component are so varied and large in comparison with the quota furnished by the body itself, independent of the food intake, that the total daily output, under the usual conditions of feeding, is not significantly modified by incidental variations in the endogenous output. The essential importance of a study of the latter feature lies in obtaining one more constant, like endogenous creatinin, from which to estimate variations incidental to disease when suitable conditions arise.

SANITATION ON THE ISTHMUS OF PANAMA AND ON THE RAND

The report by Surgeon-General Gorgas[1] on the health of the mine laborers of the Rand which appears in this issue contains data and conclusions of the highest importance. The excessive death-rate from pneumonia among the imported or "recruited" native laborers is the central theme of the report, and Gorgas' valuable and unique Panama experience has been freely drawn on for comparison. It seems that for some time the pneumonia-rate on the Rand has been very high, ranging in 1912, for example, from 26.3 in the 21,000 tropical natives to 8 in the 199,000 non-tropical. Apart from the differences associated with race or origin, the suggestive fact is noted that the newly arrived native is by far the greatest sufferer from pneumonia. In 1912, out of 2,031 deaths from pneumonia among the Rand laborers, 1,199 were deaths of men who had been at the mines less than six months. The difference between the tropical and non-tropical natives may be at bottom of the same character since, according to Gorgas, "in general, the tropical is the non-civilized native who has had little contact with the white man's diseases, and the non-tropical, the native who has had more or less contact with civilization and the white man's diseases."

[1] Gorgas, W. C.: Recommendation as to Sanitation Concerning Employees of the Mines on the Rand Made to the Transvaal Chamber of Mines, p. 1855, this issue.

Taking this fact, which seems to be the only significant epidemiologic fact shown by the Rand statistics, as a starting point, Gorgas proceeds with a masterly analysis of the pneumonia situation as observed on the Isthmus of Panama. In the construction of the Panama Canal the conditions with regard to pneumonia were at the outset very similar to those found on the Rand. In 1906 the pneumonia death-rate among the negroes brought from the West Indies to the Canal Zone was 18.74 per thousand. With the aim of reducing this very high rate a careful study was made of a number of factors that might influence pneumonia. Altitude, ventilation and the effect of sleeping in wet clothes were in turn examined as possible predisposing causes, but in each instance with negative results. "The only difference in susceptibility was shown to be governed by the length of time that the laborer had been on the Isthmus." Pneumonia was four and one-half times as frequent among the men who had been on the Isthmus less than three months as among the men who had been on the Isthmus more than three months. In the Panama Canal Zone, however, the pneumonia-rate did not remain high. The pneumonia death-rate figures are: 1906, 18.74; 1907, 10.61; 1908, 2.60; 1909, 1.60; 1910, 1.66; 1911, 2.24; 1912, 1.30. Now the significant fact is that the sudden and remarkable drop after 1907 was coincident with a radical change in the manner of living. In 1907 the negro laborers were allowed to scatter out along the line of the Canal to "build each man his hut, with a small cultivable piece of land, and bring over his family." It is evident that under such conditions the opportunities for the transfer of pneumococci from carriers to non-immunes are much less favorable than under the barrack system. Gorgas definitely attributes the sudden and permanent drop in pneumonia on the Isthmus to the scattering of the negroes in independent dwellings.

Applying these facts to the Rand situation, the conclusion is drawn that the high pneumonia-rate on the Rand is due to the same factor of barrack overcrowding which was apparently responsible for the initial high pneumonia-rate on the Isthmus of Panama. In accordance with the Panama experience the recommendation is made that so far as possible the negro laborers be allowed to bring in their families and live with them in individual buildings. Where this is not possible much roomier native quarters should be provided. The present allowance (about 14 feet of floor-space!) is much too limited.

Gorgas' conviction that under the conditions described pneumonia is a disease spread largely by contact does not seem likely to pass unchallenged, to judge from the opinion recently expressed by Maynard,[2] who deals with the same body of Rand data reviewed by Gorgas. Maynard declares that "a study of these figures shows definitely that if infections from case to case play any part in determining the prevalence of this disease among 'tropical natives,' it can be, at most, but a very small one." Nevertheless, in view of the striking course of events at Panama, it is hard to see a way of escape from the conclusions reached in Gorgas' investigation.

Gorgas' article is full of details of an unusually interesting character. In Gorgas' opinion, vaccination against pneumonia is worth considering as a protective measure. In 1912 at the Premier Mine, 17,500 inoculated had a pneumonia death-rate of 6.89, and 6,700 uninoculated a death-rate of 17.72.

Those who believe that housing is a matter of real sanitary importance[3] will find support for their views in Gorgas' opinion as to the influence of the crowded quarters on the Rand. "The general objection to such crowding is that it causes the respired air to become vitiated. My great objection to such crowding is that it forces the occupants into close personal contact, and therefore largely increases the spread of any infectious disease."

The advocates of the restriction of liquor-selling will find comfort in Gorgas' views as to the value of even localized prohibition. "Alcohol for the natives, I believe, is an unmitigated evil. It is in no way necessary for his health; in fact it is always hurtful. . . . The two Panama towns of Colon and Panama, at the northern and southern end of the Canal, are not under the jurisdiction of the commission as far as regards liquor-selling. There is no restriction on an employee going to these towns and getting liquor as he wishes and bringing it out into the Zone to his own home. The only prohibition is that it must not be sold in the Zone. But to get liquor he has to make a longer or shorter railroad trip and go to considerable effort. Our experience has shown that there are a considerable number of men who do not care enough for liquor to make the effort, and therefore do without. Of course there are a large number who bring liquor out and drink as much as ever; but on the whole our prohibition of its sale has largely decreased drunkenness. It has increased the efficiency of our working force so much that generally the men in charge of the laborers in the different districts have asked to have their districts included within the prohibited area. I believe that it would be best for the native on the Rand to have no alcohol at all."

EXPERIMENTAL PERNICIOUS ANEMIA AND ALIMENTARY INTOXICATION

The causes of pernicious anemia still remain a problem. Many have inclined to the hypothesis that gastro-intestinal sepsis may be concerned in the pathologically increased hemolysis of which all modern writers find convincing evidence. The belief that the disintegration of red blood-corpuscles is connected in some way with the toxic effect of substances generated in the alimentary tract is reflected in some of the current modes of treatment. By some clinicians active measures are employed to clear the intestinal canal more promptly and effectively than is ordinarily done. The daily washing out of the large bowel through a high rectal tube, combined with dietary measures calculated to reduce bacterial decompositions in the digestive tube, has been advocated; and beneficial results following the liberal use of laxatives have been reported. In discussing them Richard Cabot has conservatively remarked that it is not possible as yet to distinguish between *post hoc* and *propter hoc* with regard to the improvements noted.

There is little doubt that certain known intestinal parasites are capable of giving rise to severe types of anemia. Faust and Tallquist[1] isolated a hemolysin from the bodies of *Bothriocephalus*, for example; and in this case they believed that they could actually identify as oleic acid the hemolytic agent obtained from the parasites. Findings of this sort have suggested that other hemolytic anemias of man may be caused by chemical compounds which reach the blood-current via the alimentary tract. In the case just cited these hemolysins have their origin in the bodies of animal intestinal parasites. In view of the fact that in the bowel there occur at times profound bacterial changes which result in the formation of substances quite unlike those produced in normal aseptic digestion, it is a short step to charge some of these largely unknown derivatives of microbial activity with hemolytic propensities. Such vague hypotheses, however, must be substantiated or disproved by experiment

The amins have long been recognized as products of bacterial changes wrought in the proteins and their derivatives under conditions which may obtain in the gastro-intestinal tract. Many years ago Brieger of Berlin directed attention to such compounds; and two of them, putrescin and cadaverin — which are, respectively, tetramethylenediamin and pentamethylenediamin, and are genetically related to familiar protein digestion products—rank as typical so-called ptomains. Among the newer compounds of this group oxyphenylethylamin (tyramin) has become especially conspicuous of late. It has been isolated from putrid meat,[2] from certain types of cheese,[3] and —what is of especial medical interest—from ergot[4] (*Secale cornutum*). Oxyphenylethylamin is produced from the amino-acid tyrosin by various races of bacteria, among them *Bacillus coli communis*,[5] a known inhabitant of the alimentary tract of man. It is easy to conceive that disturbances in the antagonism between the micro-organisms developed in the bowel might lead to a preponderance of groups which easily produce amins of the sort represented by oxyphenylethylamin. Imidazolylethylamin (histamin) is an added case in point.

These amins are known to be endowed with pronounced pharmacologic potencies and have already found their way into therapeutics. The effects should now be ascertained not only of the heroic doses occasionally necessary in medication, but also of the far smaller quantities comparable with those which might be gradually formed and slowly absorbed under the conditions actually obtaining in the gastro-intestinal tract. An interesting beginning has been made in the medical clinic at the University of Kyoto, Japan, in Professor Sasaki's laboratory. Iwao[6] has subjected animals to repeated daily subcutaneous injections of very small doses of oxyphenylethylamin. Severe anemia of the pernicious type was thereby developed. The blood-pictures deviated strikingly from the normal.

The salts of oxyphenylethylamin do not cause hemolysis *in vitro*. The explanation of the profoundly destructive effects exerted on erythrocytes by the continued administration of this compound must lie in some process in which the damage to the blood-cells is an indirect or secondary consequence. An isolated group of experiments of this sort, however notable, is far from solving the etiology of pernicious anemia; but it represents a rational sort of experimental attack on the problem. The results show the actual production of an experimental anemia by the agency of a recognizable chemical compound of a type which can, and undoubtedly does at times, arise in the alimentary tract. The thorough study of such well-defined substances represents an intelligent way to approach the phenomena of so-called auto-intoxication.

SUGAR IN CARDIAC METABOLISM

An age of specialization has been reached in the field of metabolism. A few years ago it was the body as a whole that commanded the attention of the student of nutrition; but to-day we are learning to differentiate and recognize the special demands of individual organs and tissues. Each has its own physiologic function to perform and it is possible that each develops a special requirement for energy or the individual nutrients.

Little is known as yet regarding the gaseous metabolism of isolated organs, or of the extent to which various foodstuffs are used by them as sources of energy. It has been clearly demonstrated that incident to their physiologic work the lungs, the kidneys and other glands, skeletal muscles, heart, etc., generate carbon dioxid and require oxygen. Of late the heart in particular has been the subject of detailed investigation because it can readily be made to continue its usual action when detached from the rest of the body and perfused with circulating mediums that can be altered at will. The determination of the respiratory quotient, that is, the ratio between the carbon dioxid produced and the oxygen consumed in a given period, is an excellent index to the character of the metabolism in progress. When carbohydrates alone are burned up in the organism, the respiratory quotient $\frac{CO_2}{O_2}$ is 1; for the other foodstuffs it is lower.

The modern observations on the respiratory quotient of the isolated heart have shown it to vary within the same limits as those for the entire organism, for example, from 0.65 to 0.95 or more. This indicates that the metabolism of such an isolated organ is qualitatively closely allied to that of the body taken as a whole, or is even identical with it. In other words, the isolated heart has to a great extent the power to oxidize fully to their gaseous end-products the same cell or plasma constituents as the whole array of organs in the body has when they are working together in the normal way.

An interesting immediate confirmation of this has been furnished by Dr. C. Lovatt Evans[1] at the Institute of Physiology in University College, London. It is well known that the respiratory quotient of the entire organism is raised when carbohydrate food is taken in quantity; for this material is promptly burned in preference to other nutritive pabulum. So Evans has found that when glucose is added to the circulating blood of an isolated heart-lung preparation, the respiratory quotient of the preparation is raised. The respiratory quotient of the isolated heart is also markedly increased by previous carbohydrate diet, and it is then often decidedly higher (above 0.9) than that which is obtained after the addition of glucose to the blood. How important this dietary factor may be is indicated by the calculation that the normal heart of the dog, for example, obtains about one-third of its energy supply by the oxidation of carbohydrate. But in animals deprived of this foodstuff for some time the amount may be, and usually is, much less than this. Possibly the time may come when running expenses, so to speak, of the body's different departments can be itemized.

THE PRICE OF LABOR EXPRESSED IN TERMS OF FOOD-FUEL

As man is a fuel-consuming machine, it requires no argument to emphasize the importance of knowledge concerning the food-fuel which he needs. It matters little whether instinct is an unerring guide in providing a suitable supply of nutriment for the individual. Unless food is available at a cost within the reach of those concerned, the possibility of inadequate maintenance at once arises. The question of the undernutrition of the masses or the underfeeding of any group in society, whether it be schoolchildren, the indigent sick or the poorest laborers in the community, cannot be solved permanently before the actual nutritive needs of all of these classes are ascertained on an indisputable scientific basis. Only then is it possible to determine if the failure to obtain adequate nourishment is due, in each case, to poverty, or to the lack of suitable food-supplies or to ignorance and perverted judgment in the purchase of the day's ration.

For this reason various "standards" have been proposed by physiologists and chemists for daily dietaries of persons of differing age, sex and occupation, and in different conditions of life. In general these estimates have been based on two distinct methods of ascertaining the suitability of a ration. By the one, the quantities of food actually consumed by individuals or known groups of persons have been noted. The other method consists in determining, by special metabolism experiments, the actual physiologic demand for food. This furnishes information concerning the needs of man in maintaining a nutritive equilibrium under selected conditions of activity rather than what he would eat if given the freedom of choice. This method, being the more laborious and difficult mode of investigating dietary needs, has hitherto been employed less frequently in experimental inquiry than has the statistical method.

---

[1] Evans, C. L.: The Effect of Glucose on the Gaseous Metabolism of the Isolated Mammalian Heart, Jour. Physiol., 1914, xlvii, 407.

On the basis of the former procedure, in which the proportions of foodstuffs assumed to be needed are inferred empirically from those consumed in observed cases, nearly all of the widely quoted dietary standards have been established. Any one who hopes to interpret or employ them rationally must bear certain fundamental principles of nutrition in mind. The requirements of the body in terms of food-fuel or energy depend on the way in which food is used to build the organism and repair its waste, and above all on its heat- and power-yielding quality, particularly through the activity of the musculature. Bearing these facts in mind, it is obvious that the size of an individual is one of the factors which determine the need of food. If vigorous growth is still in progress, the demand of nutrients for new tissue construction may become noteworthy. Chief, however, stand the variations of demand caused by the unlike expenditure of energy in different occupations. The sedentary bookkeeper or seamstress requires a far smaller supply of energy than the wood-chopper or the washerwoman. It is a customary assumption that, because of her smaller average stature and lesser muscular performance, a woman requires on the average eight-tenths as much food as a man for corresponding muscular activity. It has also been assumed that children of different ages consume from three-tenths to eight-tenths as much as the man of the family. Such generalizations have become necessary whenever the food habits of people have been investigated by the observation of food purchase or consumption in entire families.

We shall not go far amiss if we express the current dietary standards, so far as they are based on the preceding mode of estimating them for conditions prevailing in the United States, in terms of the results compiled by Dr. Langworthy of the United States Department of Agriculture, as follows:

Occupation of Head of Family	Fuel Value of Food per Man per Day, in Calories
Man at very hard work	6,000
Farmers, mechanics, etc.	3,425
Business men, students	3,285
Inmates of institutions, little or no work	2,600
Very poor persons, usually out of work	2,100

Without denying in any way the importance and great value of such indirect data, one may frankly designate them as rather inexact. For this reason it is still desirable to check up their indications, whenever possible, by direct measurements of the energy transformations. Numerous results already collected by this method of investigation have given no occasion to question the general validity of the "standards" set by the less accurate statistical method. The latest of such metabolism studies is of particular interest because it was conducted under the conditions of work that represent in some adequate way the daily muscular performances of the persons concerned.[1] The experiments were conducted in the large respiration apparatus of the physiologic institute at the University of Helsingfors in Finland, the carbon dioxid output of the subjects being determined during periods of rest and characteristic activity, and calculated into terms of energy consumed. Making an allowance of 10 per cent. for the alimentary waste of food the gross results were as follows:

Men	Calories per Day
Tailor	2,600-2,800
Bookbinder	3,000
Shoemaker	3,100
Metal-worker	3,400-3,500
Painter	3,500-3,600
Cabinetmaker	3,500-3,600
Stone-cutter	4,700-5,200
Wood-cutter	5,500-6,000
Women	
Seamstress (by hand)	2,000
Seamstress (sewing machine)	2,100-2,300
Bookbinder	2,100-2,300
Housemaid	2,500-3,200
Washerwoman	2,900-3,700

These interesting figures not only give an impressive confirmation of the energy standard derived by less direct methods of investigation, but also bring into immediate, clear relief the great differences that the various trades and occupations entail. Such facts need to be taken into consideration in institutions in which the inmates are assigned to work as unlike as bookkeeping or sewing on the one hand, and wood-chopping or other forms of hard manual labor on the other. Such figures show the obvious physiologic injustice of doling out equal portions of the same ration to all of these persons, especially when free choice is restricted or practically impossible. Furthermore, it should be noted that the data of the Finnish physiologists are based on an eight-hour working day. Any lengthening of this period must affect the expenditure here represented.

It is impossible to determine from the cursory studies that have been made whether the scale of living or "standard of life" is actually much higher here, as has been asserted by some, than it is in Europe. One American authority, the late Professor Atwater, frankly believed that, considering the body as a machine, the American workingman is more strongly built and has a larger fuel-supply than his European brother. While it is not absolutely proved, it seems in the highest degree probable that the higher standard of living, the better nutrition, the large product of labor and the higher wages go together. The justification for any propaganda in favor of more liberal standards for dietaries rests in a measure on the truth of this belief. And, speaking aside for the moment, a glance at the figures which we have quoted shows that the proverbial advice to "mind one's business and saw wood" entails no mediocre performance in terms of calories per day.

SOME CONDITIONS INDUCING EXCESSIVE RESPIRATION

It has been pointed out by several investigators[1] that voluntary forced breathing in man may give rise to unpleasant and even alarming symptoms. The outcome apparently depends on a number of modifying factors. As a rule, in a short time after the forced breathing the subject either stops breathing altogether if his respiration is allowed to act involuntarily or he breathes in a very shallow and ineffective manner. Numbness and tingling in the hands and feet are reported to occur; and if the forced breathing has been of considerable duration — two or three minutes or longer — many subjects experience an oxygen want when the subsequent apnea sets in. The lips may turn blue; Cheyne-Stokes breathing may be initiated; and Henderson has called attention further to the occurrence of "light-headedness," polyuria, shivering, muscular weakness and other functional disturbances induced by prolonged forced breathing. He maintains that the symptoms evoked are similar to those of shock, and suggests that death from failure of respiration would probably result from vigorous voluntary hyperpnea for fifteen or twenty minutes.

There are various ways in which excessive respiration — hyperpnea — can be induced in man aside from the purely voluntary manner that has just been referred to. Pain is one of the natural stimuli calling forth hyperpnea. Anger, sorrow, fear and ether-excitement may induce a similar result. All of these phenomena may be attended or followed by what is sometimes spoken of as shock. Henderson, as is well known, has argued that the condition of shock which results in man from extreme physical suffering is, to a large extent, caused by the reduction of the carbon dioxid content of the blood and tissues as the result of the violent and prolonged hyperpnea caused by stimulation of afferent nerves. In contrast with this is the view that the ill effects produced by suffering are the expression of fatigue of the nervous system and of the heart, resulting from the intensity of the sensory irritations. This theory of the etiology of shock has been vigorously combated. We have no desire at this time to enter into a discussion of the nature of this much-debated subject. The underlying facts with respect to the physiologic effects of pain and ether, for example, on the respiration in man ought to be demonstrable quite independent of the interpretation which is put on the consequences thereof.

Hitherto much of the experimental work has been conducted on animals under conditions which approached extremes rarely found in man; or in the case of experiments on man the voluntary forced respiration has been somewhat unlike that which might arise in the exigencies of practice. Dr. A. L. Meyer of the University of Pennsylvania has approached the problem of hyperpnea and acapnia in its possible relation to "one of the most important symptom-complexes in medicine" by a direct study of the effect of moderate pain and of the incipient stage of anesthesia in man. In Haldane's laboratory at Oxford he determined the volume of air breathed, the respiratory exchange, and the alveolar carbon dioxid pressure on human subjects.[2] The device for securing experimentally the effect of moderate pain, the duration of which could be controlled, consisted in placing a clamp on the end of the little finger. This apparatus could be screwed down firmly and then released. The average pain was, according to the investigator, probably such as might be caused by a severe felon.

Pain of moderate intensity and short duration (two to three minutes) actually produces hyperpnea that can easily be measured. The alveolar carbon dioxid is diminished and the respiratory quotient increased. Ether in suitable low concentration produces hyperpnea in one minute. How vigorous it may become is illustrated by one case in which an air mixture containing 3.3 per cent. of ether produced an increase of 92 per cent. in the air respired; and on another occasion a mixture of 2 8 per cent. produced an augmentation of 66 per cent. The degree of excessive ventilation of the lungs varies in different persons; and with higher concentrations of ether the breathing is diminished. The alleged possibilities of inducing acapnic conditions in man are accordingly established.

Current Comment

GOING TO ATLANTIC CITY?

The Journal for May 16 contained a preliminary announcement of the program for the Scientific Assembly and detailed information with regard to hotel accommodations at that city of hotels—Atlantic City. Before the next issue of The Journal reaches its readers, many members and Fellows will be on their way to the meeting-place. If arrangements have not already been made there is still time to complete them and to take advantage of the session. The usual large attendance undoubtedly will be increased because of the hot weather which prevails, making Atlantic City especially attractive. Even apart from the interesting scientific program of the Sections, Fellows who go will be well repaid by meeting and exchanging ideas with professional brethren from all over the country, including the leaders and men in the forefront of investigation and research. Then, too, the setting of the meeting will be ideal: abundant comfortable hotel accommodations managed by men who are past masters in the art of providing for the comfort and pleasure of their guests, and the local profession who have always proved themselves gracious hosts and who have solved the problem of caring for heavy professional duties and at the same time greeting visiting physicians with a heartiness that assures all a welcome — all this has been the experience in the past, and Atlantic City improves every time the Association pays it a visit. It requires no gift of prophecy to foretell a delightful social good time, as well as a scientific treat. The Fellows who go to Atlantic City will work the better throughout the year for having thrown aside the routine and the demands of a busy practice for this short breathing-space.

[2] Meyer, A. L.: Hyperpnoea as a Result of Pain and Ether in Man, Jour. Physiol., 1914, xlviii, 47.

THE SPREAD OF THE "SANE FOURTH" MOVEMENT

Probably at no time in the eleven years since The Journal began its agitation for a safe and sane Fourth has so much interest been manifest in such a number of cities so far in advance of our national holiday. Information from all over the country indicates that those cities in which our last year's report showed a high death- and accident-rate are bestirring themselves in the hope of preventing the repetition of last year's experience. As has been frequently pointed out, the city is directly responsible for the regulation of the Fourth and the prevention of the needless slaughter, maiming and blinding of children. Municipal ordinances are the only method by which this problem can be solved. In the report issued last August, The Journal showed that the total price in human life and suffering paid for the celebration of the Fourth of July during the past eleven years was 1,792 deaths and 39,488 injuries; that, although the number of injuries and fatalities had decreased during the past four years, the cities in which the old and barbarous methods of celebrating the Fourth were still followed, were maintaining or were even exceeding the records of previous years in the quota of deaths and injuries. Thus, while New York had reduced its record from 22 killed and 422 injured in 1907 to none killed and 65 injured in 1913, and Chicago during the same period had fallen from 16 killed and 151 injured in 1907 to 1 killed and 12 injured in 1913, Philadelphia, which had 7 killed and 248 injured in 1907, had 3 killed and 340 injured in 1913. What New York and Chicago have done, Philadelphia can do if she will. The death or injury of her children from Fourth of July accidents is a matter for which each city government is directly responsible. Other cities in which the number of killed and injured is still far too high are Pittsburgh, Cincinnati, Providence, R. I., Worcester, Mass., Syracuse, N. Y., Omaha, Neb., Grand Rapids, Mich., Hartford, Conn., Reading, Pa., Wilmington, Del., and Des Moines, Ia. The citizens of these cities would do well to demand from the city government, for the protection of their children, the passage of ordinances that will prohibit the sale of fireworks, and substitute for the former barbarous methods of celebration plans more in keeping with the day and the occasion which it commemorates.

TEACHING IN MUNICIPAL HOSPITALS

As we have remarked before,[1] a large hospital which does no more than care for the sick fulfils only a part of the function it owes to the community. It should contribute its share to medical education and research, and should therefore stand in such relation to a teaching institution as will permit the best possible use of the clinical material it affords. Many private hospitals and the state hospitals of Virginia, Michigan and Iowa have arranged such connections. We mentioned last week[2] that Yale Medical School, according to the terms of a gift made by the General Education Board of the Rockefeller Foundation, is called on to acquire control of the New Haven Hospital with its 260 beds. If the conditions of the gift are fulfilled, Yale will be the fifth medical school in this country to acquire control, by definite agreement, of the municipal hospital facilities in the community in which it is located. The Cincinnati Hospital with its 500 beds is utilized for clinical instruction by the College of Medicine of the University of Cincinnati. The medical department of the University of Georgia, by contract with the city of Augusta, has control in perpetuity of all the municipal hospitals now in existence or hereafter to be erected in that city. The medical department of the University of Louisville is able to make use of the clinical material afforded by the Louisville City Hospital with its 500 beds. The School of Medicine of Western Reserve University has control of the clinical facilities of the Cleveland City Hospital and St. Vincent's Charity Hospital, in addition to those afforded by private hospitals — in all, over 1,300 beds. In various other cities, the municipal hospital facilities are utilized for instruction to a greater or less extent under less formal arrangements. In marked contrast with such arrangements with hospitals elsewhere is the withholding from use in medical teaching of the abundance of splendid clinical material in the 1,700 beds in the great Cook County Hospital in Chicago. That the best interests of hospital patients are thus sacrificed is clear, since it has long been recognized that the highest standards of efficiency are found in those hospitals which are most closely related with high-grade medical schools. It is only through such relationships that the hospitals are kept in touch with the latest and best methods of diagnosis and treatment, since they aid in and get the benefits of the research work of the medical school. The public interests are likewise sacrificed in the lack of such a relationship, since one of the main functions of the hospital is not being exercised, namely, that of supplying material for the training of future nurses and doctors, who in turn would be stimulated to greater zeal in the recognition, treatment and prevention of diseases. It has repeatedly been shown that physicians are invariably more careful in their methods of diagnosis and treatment if they are being watched by a few bright, intelligent medical students. It is to be hoped that the closer relationships being established between private and municipal hospitals and leading medical schools elsewhere may point the way to similar relationships in Chicago and our other large cities.

THE DOCTOR'S DILEMMA

The other day a physician of Duquoin, Ill., was shot to death because he refused to answer a call to the family of the murderer. Such, at least, is the newspaper report, and it is probably correct. The following morning the Chicago *Tribune*, under the caption "The Doctor's Dilemma," contained an editorial that is so sensible and recognizes the situation so well that we quote it entire:

> When a child becomes sick at night the first thing the anxious parents think of is the doctor. They have no hesitancy to wake him up before dawn. They will drag him out of the house before breakfast. The few minutes he takes to dress seem ages to them. If they could they would transport him on wings to their sick child's bedside.
>
> But just as the doctor is thought of first in illness, he is thought of last after the patient has recovered. Doctor bills are postponed to the last. In no profession or business is the amount of unpaid bills as great as in the medical profession. It is not surprising that a doctor now and then scorns a call from a family he has down on his list as "dead beats."
>
> For scorning a call from a family that had not paid him for services previously rendered, a physician was killed the other day by the irate head of this family. No doubt the slayer of the physician will try to defend his action on the ground of having been crazed by the sufferings of his child. But it will be a false defense. It was murder pure and simple. And the unreasonable attitude which the public takes toward the physician is in part responsible for it. We are too apt to forget that the doctor has rent to pay and grocer bills to meet.

OXFORD HONORS SURGEON-GENERAL GORGAS

By a peculiarly happy coincidence we are able to present, in connection with Surgeon-General Gorgas' paper, "Recommendation as to Sanitation Concerning Employees of the Mines on the Rand," facsimiles of two interesting documents. These are the copies, which Sir William Osler caused to be engrossed and illuminated on parchment, of the addresses made at Oxford when the honorary degree of Doctor of Science was conferred on Dr. Gorgas. The beautiful colors of the originals, however, must be left to the imagination. On page 1864 is a facsimile of the address of the public orator of Magdalen College, Oxford, on the presentation of Dr. Gorgas for the degree, together with an exact transcript of the translation which is engrossed on the same parchment. The latter, by the way, contains in the beautifully executed original, and hence in the transcript, a few easily recognizable typographical errors, evidently made by the artist who did the engrossing. On the opposite page is a facsimile of the address of the acting vice-chancellor, who, in admitting Surgeon-General Gorgas to the degree of Doctor of Science, addressed him as:

> Preeminently distinguished, sagacious, health-bringing, the modern Machaon of the American Army, whom indeed I should wish to salute not only in Latin prose but also in Greek verse thus:
>
> "Hail Router of the Plague of Flies! Hail Isthmian Conqueror true!
> Gorgas, to that wise Goddess dear, the Gorgon death who slew!"

There was a time, as these addresses remind us, when mighty works like those done at Panama would have been celebrated in heroic legend and epic verse; when the hero who freed one of the gateways of the world from a subtle and myriad-winged death would have been deemed to be directly inspired by the Goddess of Wisdom herself. Nay, more, his very name, as the acting vice-chancellor's charming Greek verses suggest, would have enshrined a mystery for the philologists of later days, who would have gravely shaken their puzzled heads as they endeavored to trace the undoubted connection or identity of the Isthmian Gorgas with the earlier Gorgon-slayer, the hero Perseus! To-day the "Epic of the Isthmus" waits for the poet who shall arise

> Chanting of order and right, and of foresight, warden of nations,
> Chanting of labor and craft and of wealth in the port and the garner.

Meanwhile, it is a source of national satisfaction to Americans to see the knowledge and skill that made possible the Panama Canal employed on similar tasks in Africa and honored in one of the great universities of England.

THE PSYCHOLOGY OF MARINE DISASTERS

With the great increase in size and speed of passenger steamers there has come no such diminution of risk of life as some of us perhaps anticipated. Indeed, when the carrying capacity is increased, the loss of life in each wreck or disaster is necessarily greater. Cellular sides and other ship-building safeguards are evidently no real insurance for ships against mortal injury, even when the perils of storm and speed are eliminated as they apparently were from the late St. Lawrence River disaster. Study of the personal factors in and the possible psychologic causes for these shipwrecks is therefore of chief importance. The rules of the road at sea are simple, and when two vessels, each pursuing a correct course, sight each other and a few minutes later, cut off by fog, come into collision, the inference is that some one has made a serious blunder. A wrong order or a right one misunderstood under such circumstances may have terrible consequences. Sometimes the order is unaccountably wrong, as in the case of the British battleship *Victoria* about ten years ago, but the disaster may also be the result of the careless or thoughtless misinterpretation of a correct order by the wheelsman, to whose hand the modern steering-gear so quickly and accurately responds. As the collision between the

Empress of Ireland and the collier *Storstad* occurred during a fog, the question of color-blindness does not come into consideration. It would seem that a thorough investigation by experts might reveal personal defects aside from the purely mental factor responsible for such occurrences. The question is not a new one; it has been generally and extensively discussed many times, but these repeated disasters should arouse a demand for a specific and thorough investigation of every possible factor.

Medical News

COLORADO

New Officers.—El Paso County Medical Society at Colorado Springs, May 17: president, Dr. Beverley Tucker; secretary-treasurer, Dr. Elmer L. Timmons, both of Colorado Springs.

After the Quacks.—The *Rocky Mountain News* is conducting a campaign against the quacks that infest Denver. It not only refuses their advertisements, but has been investigating their methods of doing business. As a counter proposition the quacks, it is stated, have been attempting to secure information on which to base charges of irregular practice against the members of the State Board of Medical Examiners. *The plan was to hire a detective to go to the physicians* of the state board soliciting treatment for diseases which he did not have. It is believed the publicity will act disastrously on the fraudulent business of the quacks. It is believed there is still room for improvement in the advertising matter carried by the *News*. The *Denver Express* has also announced its purpose to refuse medical advertisements of all kinds at the expiration of present contracts.

CONNECTICUT

Refuge for Cardiac Convalescents.—In July of last year a convalescent home was opened at Sharon, intended exclusively for patients suffering from heart disease or convalescing from acute attacks. In connection with this institution there is established a trade school for cardiac convalescents. The object of this philanthropic work is to provide an industry whereby these convalescents may earn a living, without incurring grave risk. Each workman is graded in accordance with the amount of work he may safely do, and this is increased as the crippled heart recovers. Rest rooms are provided, and there is constant medical supervision. The industry established at Sharon is the making of concrete flower-pots.

Yale Centennial.—At the commencement of Yale University, June 15-17, Yale Medical School will celebrate the one-hundredth anniversary of the first conferring of degrees. The occasion will be observed by special exercises at which addresses will be presented by Prof. William H. Howell of Johns Hopkins University and Dr. Walter R. Steiner of Hartford. On commencement day a number of honorary degrees will be conferred to commemorate the occasion. A life of Nathan Smith, one of the founders of the school, will be issued from the Yale University Press at about commencement time, and a memorial volume of medical papers, prepared under the editorship of Dr. Horst Oertel, and containing contributions from Drs. Graham Lusk, E. R. Baldwin, John Hartwell, C. W. Field, W. W. Herrick, Charles F. Craig, Samuel W. Williston and Horst Oertel, will appear as a special number of the *Archives of Internal Medicine*. It is hoped that the university will be able to announce at this time the consummation of the plan for affiliation with the New Haven Hospital and gifts to the endowment of the school.

ILLINOIS

Murdered by Non-Paying Patient.—Dr. D. Winton Dunn, formerly mayor of Duquoin, was shot six times by a coal-miner, June 6, and died as a result of his wounds while being taken to a hospital in St. Louis. The murderer is said to have stated his reason for the act was he owed Dr. Dunn a bill for professional services, and that Dr. Dunn had refused to make further calls until the bill was paid.

Alumni Elect.—At the annual meeting of the Alumni Association of the Northwestern University Medical School, held in Chicago, June 8, the following officers were elected: president, Dr. Frederic A. Besley, Chicago; vice-presidents, Drs. William H. Fitch, Rockford, and Edward Von Hess, Chicago; secretary, Dr. Arthur B. Eustace (reelected); treasurer, Dr. Leo G. Gwan (reelected); and necrologist, Dr. Samuel C. Stanton.

State to Make Wassermann Test.—The governor has approved plans laid before him by Dr. C. St. Clair Drake, secretary of the State Board of Health, for the material extension of the laboratory department of the board. It is announced that the Wassermann blood-test will be made free of charge for indigent patients, and that microscopic examinations of cultures in cases of diphtheria will also be made under the same conditions.

Personal.—Dr. Lee O. Scott, Rockford, is reported to be critically ill.——Dr. Charles E. Cole, Jacksonville, sailed for Europe June 9.——Dr. Charles H. Bacon, Lockport, is reported to be critically ill in St. Joseph's Hospital, Joliet.——Drs. Frederick E. Roberg, Joliet, and Oscar T. Roberg, Chicago, have sailed for Europe, for a tour of the world.——Dr. Walter C. Jones has been reelected president, and Dr. Ernest J. Ford reelected treasurer of the Evanston Tuberculosis Institute.——Dr. Oscar P. Harris, Mendota, has opened a hospital in that city.——Dr. Gustav F. Ruediger has been elected health commissioner, and Dr. Oric C. Yoder, Peru, assistant health commissioner, of La Salle.

Chicago

Memorial to Fenger.—The Danes of Chicago, at a meeting, June 7, adopted a resolution endorsed by the Danish National Committee, requesting that a memorial tablet to Dr. Christian Fenger, for many years chief of the surgical staff of the Cook County Hospital, be placed in the new County Hospital.

Personal.—Dr. Lewis L. McArthur, who has been seriously ill at his home, is reported to be convalescing.——Dr. Peter S. Winner has been appointed physician of the State Penitentiary at Joliet, vice Dr. John P. Benson.——Drs. Peter J. Latz and Adolph Hartung have sailed for Europe.——Dr. Isaac J. K. Golden fractured his left arm and sustained other injuries, June 3, in a collision between his motor-car and an auto-truck.——Dr. Francis W. McNamara has been appointed county jail physician, vice Dr. Thomas J. Hogan.

KANSAS

Summer School.—The School of Medicine of the University of Kansas held its fourth annual summer school for physicians and health officers, under the auspices of the Kansas State Board of Health and the School of Medicine, at Bell Memorial Hospital, Rosedale, June 8-13, inclusive. The work of the school included clinical and laboratory work, and discussions of public health problems. Each day a round-table conference for health officers was conducted by Dr. R. J. Crumbine, secretary of the State Board of Health. The entire course was free to any licensed physician, student of medicine, or legal practitioner of the state.

MARYLAND

Anniversary of John Hopkins Hospital.—The twenty-fifth anniversary of the opening of Johns Hopkins Hospital, Baltimore, will be celebrated with appropriate exercises the first week in October. The preliminary program provides for addresses and papers by a number of well-known clinicians and teachers, as well as by graduates of the Johns Hopkins Medical School.

Personal.—Dr. Philip Briscoe, Mutual, has been elected president of the State Board of Aids and Charities. The board has named a committee to study the question of cooperative purchasing by the institutions which receive state aid, of which Dr. J. H. Mason Knox, Baltimore, is a member.——Dr. Nathan R. Gorter, the Commissioner of Health, has appointed Dr. Alexander J. Gillis assistant superintendent of Sydenham Hospital, to succeed Dr. Walter W. Point, Jr., Baltimore.——Dr. Gustav H. Woltereck has been appointed throat inspector in place of Dr. Wilbur P. Stubbs, recently named as a medical examiner of schools.——Dr. Adolf Meyer, Baltimore, has been appointed a member of the board of managers of the Maryland Training School for Girls.——Dr. Ralph R. Browning, Myersville, has been elected health officer of Frederick County, vice Dr. James M. Goodman, Frederick.——Dr. A. Lee Hichew has been appointed medical supervisor of the Franklin Square Hospital, Baltimore, to succeed Dr. G. S. La Wall.

MASSACHUSETTS

Trachoma in Boston.—Two steerage passengers suffering from trachoma were found on the steamship *Caledonia* which arrived in Boston from Manchester, May 28, and three passengers with the same disease were found on the steamship *Michigan* which arrived at Boston from Liverpool on the same day. All the afflicted passengers were Syrians.

Tufts Alumni Elect.—At the twenty-first annual meeting and banquet of the Alumni Association of Tufts Medical School, Boston, the dean, Dr. Charles F. Painter, was the guest of honor and principal speaker. The following officers were elected: president, Dr. Herbert A. Donnell, Medford; vice-presidents, Drs. Bessie D. Davis, Cambridge, Russell B. Sprague, Boston, Anna O. Sullivan, and Isador H. Coriat, Boston; secretary, Dr. Andrew P. Cornwall, Boston, and treasurer, Dr. James F. Coupal, Boston.

MICHIGAN

New Officers.—Detroit Oto-Laryngological Society, May 26: president, Dr. Emil Amberg; secretary-treasurer, Dr. Charles L. Chambers.

Automobile Manufacturer to Build Hospital.—In a letter to the directors of the Detroit General Hospital, Henry Ford announces his willingness to take over the property on West Grand Boulevard, to complete the work, and to provide Detroit with a first-class hospital. This entails an expenditure of $3,000,000, and Mr. Ford agrees to repay every subscription that has been made toward the building fund of the hospital.

Half a Million for Hospital.—On May 18, in the presence of the members of the medical fraternity and the board of directors of the Union Benevolent Association Hospital, Mr. John W. Blodgett turned the first spadeful of earth for the excavations of the new U. B. A. Hospital, the gift of Mr. Blodgett. The specifications call for a concrete building, and the contract has been awarded for $559,000, the building to be completed by December 15.

New Medical Society.—At a banquet given by the Bay County Medical Society, May 18, the first steps were taken toward the formation of the Saginaw Valley Academy of Medicine, and a committee consisting of Drs. James W. McMeckin, James D. Bruce and Henry J. Meyer, Saginaw; John W. Hauxhurst, Frank E. Ruggles and W. G. Kelley, Bay City; and Knapp, Herbert E. Randall and Robert D. Scott Flint, was appointed to work out plans for organization.

Personal.—Dr. Joseph J. Noeker, Detroit, is reported to be seriously ill with tuberculosis at his home.——Dr. Charles E. Boys, Kalamazoo, left for Europe, June 1.——Dr. James T. Case, Battle Creek, has been made a member of the X-Ray Society of Germany.——Dr. John H. Kellogg, Battle Creek, has received a gold medal and diploma from the University of Italy, Palermo.——Jackson County Medical Association gave an informal reception and supper at Jackson in honor of Dr. Nathan H. Williams, who is moving to California.——Dr. Harry W. Long, Escanaba, sails for Europe this month.

To Celebrate Semi-Centennial.—Medical men of Detroit met in the Wayne County Medical Society's banquet hall, May 19, to commemorate the half-century of professional life of Dr. Charles Douglas. Dr. J. Henry Carstens was toastmaster and speeches were given on the various phases of the personal and professional life of Dr. Douglas. Dr. Angus McLean spoke on Dr. Douglas as "The Man," Dr. Arthur D. Holmes as "The Pediatrician," Dr. John E. Clark as "The Teacher," Dr. Daniel La Ferte as "The Colleague," Dr. Eugene Smith as "The Family Doctor." Dr. N. L. Hooker responded to the toast: "Dr. Douglas and the Young Doctor," and Dr. Douglas spoke on "Our Guest, By Himself." After the banquet, Dr. Douglas was presented with a gilt-ivory clock, suitably inscribed.

NEVADA

Hospital Opens.—Mount Rose Hospital, Reno, was opened May 22. The building is well located and fully equipped, and is under the charge of Miss Higerty, formerly nurse in St. Mary's Hospital, Reno.

Personal.—Dr. and Mrs. John E. Pickard, Reno, have started for Europe.——Dr. Harry G. Knapp, Fairview, has located at Wonder.——Dr. John C. Kitchen, Aurora, has severed his relations with the Aurora Mining Company, and has been succeeded by Dr. John B. Edwards, Mason.——Dr. William N. Burdick, Goldfield, has moved to Arizona.——Dr. Ora B. Dunham, Goldfield, has moved to San Diego, Cal.——Dr. Henry D. Hargrave, Reno, has returned to his old home in Toronto, Ont.——Dr. John L. Robison, Reno, has started for Europe.

NEW YORK

New Officers.—Washington County Medical Society at Whitehall, May 20: president, Dr. Willis A. Tenney, Granville; secretary, Dr. Silas J. Banker, Fort Edward.——Saratoga Springs Medical Society at Saratoga Lake, May 23: president, Dr. Fred J. Resseguie; secretary-treasurer, Dr. Miles E. Van Aernem.

Buffalo Alumni Meet.—The thirty-ninth annual meeting of the Alumni Association of the University of Buffalo was held June 2-5. On June 2, 3 and 4, the Harrington lectures on "Recent Advances in Pathological Anatomy" were delivered by Prof. Ludwig Pick, of the University of Berlin, Germany. On June 4, the first hour was given to memorial exercises in honor of Drs. Roswell Park and Frederick C. Busch. On June 5, the commencement exercises were held.

Scarlet Fever Epidemic at Auburn.—The epidemic of scarlet fever in the Auburn prison has reached large proportions. It is said that thus far in the inspection more than 1,000 inmates have shown signs of infection. The epidemic started in the women's prison but has spread to the men's as well. There are very few ill enough to be confined to bed. The prison contains no hospital accommodations for a general epidemic and the isolation of suspects is impossible.

Personal.—Dr. Harry S. Bernstein, director of the Bender Hygienic Laboratory at Albany has been appointed pathologist and bacteriologist to the Rhode Island Board of Health and will assume his new duties September 1.——Dean Willis G. Tucker, at the annual dinner of the alumni of Albany Medical College, held May 26, was presented with a silver loving-cup in recognition of his services as registrar of the college for 32 years, from which position he retired on January 1 last.

Club House for Physicians.—The Rochester Medical Society has purchased the property at 33 Chester Street and will alter it and fit it up for a club-house. The purchase price was $35,000, of which $18,000 has already been subscribed by local practitioners. It is expected that the building will be ready by September. Dr. William B. Jones is president; Dr. Frank F. Dow, vice-president; Dr. David B. Jewett, secretary, and Dr. Wesley T. Mulligan, treasurer of the board of directors.

New York City

Personal.—Dr. Robert Abrahams has been elected president of the board of managers of the Manhattan State Hospital, Ward's Island.——Dr. Charles F. Bolduan has been appointed head of the new Bureau of Public Health Education, of the Department of Health.——Dr. L. Emmett Holt has been appointed consulting pediatrician of the Department of Health.

Baby Week Planned.—The Department of Health, with the approval of Mayor Mitchel, is laying plans to keep one week in June as "Baby Week." It is proposed during that time to interest everyone in the public and private agencies which care for babies during the summer months and are assisting in the effort to lower the infant mortality. It is pointed out that the death-rate of infants in New York City has been reduced during the last seven years from 135.8 per 1,000 to 101.9 and that a still lower rate is possible.

Annual Memorial Meeting.—The memorial meeting of the Kings County Medical Society was held at their headquarters, May 31. The roll-call of the deceased members was as follows: Drs. George R. Westbrook, Robert E. Moore, John R. Stivers, Albert T. Birdsall, George Drury, Stanley MacGillvary, George McNaughton, Eugene F. Pearce, Edward W. Carhart, Jesse W. Henry, M. J. Leland, William H. Clowminzer, James L. Watt, Henry C. Turner, Norman E. Farewell, Francis M. Burke, Francis S. Kennedy, Annie M. Brown, and Daniel W. Woolley.

Vaccination Law Upheld.—Some time since Haghard Eckerbold, a resident of the Bronx, was fined five dollars for violation of the compulsory education law, as he had refused to have his child vaccinated and the authorities would not permit the child to attend school under those circumstances. The court of apppeals has affirmed the judgment of the lower courts holding that the laws requiring vaccination as a condition of attending public schools were not so unusual or oppressive as to excuse the defendant's act. The court also referred to the fact that the United States supreme court recently held constitutional a statute compelling vaccination.

Mikveh Baths.—A conference was recently called by Dr. Sigismund S. Goldwater, Commissioner of Health, to consider the matter of the "Mikveh" baths or cleansing pools whose regular use is required by the Jewish faith. An independent bacteriologic investigation conducted by Dr. George Mannheimer of Columbia University has shown that as at present conducted these baths are a menace to the health of those using them and points out the need of steps to render them sanitary. The problem has been presented to the Board of Authoritative Rabbis with the request that they suggest plans for making the baths sanitary to the Health Department in the near future.

New Appointments at Columbia.—The trustees of Columbia University at their meeting, June 1, appointed Dr. Warfield T. Longcope Bard, professor of the practice of medicine to succeed Dr. Theodore C. Janeway. Professor Longcope was also nominated medical director of the Presbyterian Hospital. The department of therapeutics has been merged with that of clinical medicine and Dean Samuel W. Lambert, formerly professor of therapeutics, has been appointed professor of clinical medicine. Dr. Charles C. Lieb has been appointed assistant professor of a new department of pharmacology and Dr. William Darrach has been appointed assistant professor of surgery. A gift of $2,400 from various donors has been presented for a scholarship at the College of Physicians and Surgeons in memory of the late Frank A. Hartley.

Urges Health Work on Life Insurance Companies.—At the meeting of the Association of Life Insurance presidents held in this city, June 5, Dr. Louis I. Dublin, statistician of the Metropolitan Life Insurance Company, presented figures showing that while the death-rate throughout the country has been lowered, the amount of illness has not been lessened to any appreciable degree. He estimates that the annual losses from preventable illness in the United States is $1,000,000,000 annually. The next twenty years must see our efforts directed to the control of disease and for this reason he urged the passage of a bill drafted by the state health officers at a conference in 1913 to insure complete reports of diseases. It was urged that the life insurance companies should assist by having this bill put on the statute books of the states by cooperating with committees appointed for the purpose by the American Medical Association and the American Public Health Association.

NORTH CAROLINA

Personal.—Dr. William E. Earley, Marietta, has been appointed United States Consul to Leicester, England.——Dr. Hugh E. Bowman, Biscoe, has moved to Aberdeen.

District Society Meeting.—At the semi-annual meeting of the Second District Medical Society at New Berne, N. C., May 26, Dr. William E. Warren, Winston, was reelected president, and Dr. Kemp P. B. Bonner, Morehead, secretary.

Medical School will No Longer Confer Degrees.—At the commencement of Shaw University Medical School (Leonard Medical School, Raleigh), May 13, the announcement was made that, beginning with the next session, the university would give only the first two years of the medical course and would cease to confer medical degrees.

State Association Meeting.—The sixty-first annual meeting of the Medical Society of the State of North Carolina will be held in Raleigh, June 16-18, under the presidency of Dr. J. James M. Parrott, Kinston.——The North Carolina Public Health Officers Association will hold its fourth annual meeting at Raleigh, June 15, under the presidency of Dr. J. M. Cooper, Clinton.

Hospital Notes.—Plans have been completed and construction work will shortly begin on the new Catholic hospital in Charlotte. The central portion will accommodate forty patients, but the plans call for the construction of additional units which will afford space for 100 patients.——A 10-acre site in Gastonia has been offered the directors of the recently chartered Orthopedic Hospital as a site for the proposed institution by the Rev. A. T. Lindsay, president of Linwood College, Gastonia.

OKLAHOMA

Meeting of Colored Physicians.—The Oklahoma Medical, Dental and Pharmaceutical Association, an organization of colored men, held its annual meeting at Tulsa, recently. Dr. W. B. Humphrey, Sapulpa, was elected president. The next meeting will be held in Wewoka.

Personal.—Dr. Dumont W. Howell, Nowata, who recently sustained a fracture of the thigh, is convalescent and will soon leave the hospital at Kansas City.——Dr. Franklin G. Trigg, Lovell, was assulted recently, and his left index finger bitten off.——Dr. Robert L. Rhodes, Tulsa, has been appointed physician of Tulsa County, vice Dr. James E Webb, resigned, to become city physician of Tulsa.——Dr. Roy K. Goddard, Supply, has been appointed assistant superintendent of the Supply State Hospital.

OREGON

New Officers.—Clackamas County Medical Association at Oregon City, May 28: president, Dr. John W. Norris; secretary-treasurer, Dr. Carl H. Meissner, both of Oregon City.

Alumni Reunion.—At the alumni reunion of the University of Oregon, clinics and laboratory demonstrations were held on June 2, 3 and 4. The annual business meeting and banquet of the association were held June 2 at the Multonomah Hotel, Portland.

Personal.—Dr. David N. Roberg, Portland, as a representative of the State Board of Health, is making a study of plague conditions in the Orient.——Dr. Charles W. Tidball, Portland, has been awarded a bronze medal and $1,000 in money by the Carnegie Hero Foundation, for his rescue of a woman from drowning in Independence River, Mo., in 1911.——Dr. Thomas J. Higgins, Baker, has been appointed as a member of the State Board of Health, vice Dr. Charles J. Smith, Portland.

PENNSYLVANIA

Hospital Dedicated.—The new building of the Monongahela Memorial Hospital was dedicated, May 30, with appropriate ceremonies.

New Officers.—At the meeting of the Pittsburgh College of Physicians, held May 27, the following officers were elected: president, Dr. Thomas W. Grayson, Pittsburgh; vice-president, Dr. Dewitt B. Nettleton, Sewickley; secretary, Dr. George A. Holliday, Pittsburgh, and treasurer, Dr. Curtis C. Mechling, Pittsburgh.

Commencement Week Clinic.—The School of Medicine of the University of Pittsburgh has arranged a clinical program in connection with the exercises of commencement week. Special clinics will be held in hospitals affiliated with the university, and laboratory demonstrations in the buildings on the university campus.

Save Children's Eyes.—Under a new state law all cases of ophthalmia neonatorum must be reported to the Bureau of Health. The law requires that any midwife or nurse, or any other person having the care of an infant whose eyes become inflamed or swollen, or reddened any time after two weeks after birth, shall report the same in writing to the health authorities within six hours.

Personal.—Dr. W. Knowles Evans, Chester, has been appointed superintendent of the new Health Department, made possible by the Clark act.——Dr. George G. Gill, assistant physician at the Hillside Home, Scranton, has resigned and will practice at Butler, N. J.——Dr. Gregg A. Dillinger, Pittsburgh, has been appointed chairman of the Public Safety Committee of Council as a member of the Public Morals Bureau.——Dr. W. Knowles Evans has been elected supervisor of the Health Department of Chester.

Railroad Accidents.—The accidents division of the public service commission, issued its report for the first quarter of 1914, May 31, which shows that 262 persons were killed on the steam railroads of the state and 2,480 injured. This is a decrease of 18 in the number of fatalities compared with the same period of last year, and a decrease of 2 as to the number injured. There were 29 killed on street railways and 725 injured. Those fatally injured on the railroads were 98 employees, 2 passengers and 146 trespassers. Those killed on street railways were 4 employees, 1 passenger, 3 trespassers and 21 others.

Philadelphia

Alumni Reunion.—The annual reunion of the Alumni Society of Philadelphia of the Medical Department of the University of Pennsylvania, was held at Glenrock Park, N. J., June 4.

Alumni Elect.—At the annual meeting of the Alumni Association of the Jefferson Medical College, June 5, the following officers were elected: president, Dr. Francis T. Stewart; vice-presidents, Drs. J. Coles Brick, John H. Gibbon, E. Q. Thornton, P. Brooke Bland; corresponding secretary, Dr. Elmer H. Funk; recording secretary, Dr. Walter S. Lucas, and treasurer, Dr. Warren B. Davis, all of Philadelphia.

Model Homes.—Plans for the erection of a group of model dwellings in Kensington, were announced June 4, by the Octavia Hill Association. The new dwellings will be build of brick, two stories high and will be so arranged that families will be able to rent two rooms for $6.50, three rooms and a bath for $10 and a separate house of four rooms for $13 a month. These houses will be arranged around an area of nearly one-third of an acre, and this open space will be filled up as a playground.

College Commencements.—The sixty-second annual commencement of the Women's Medical College of Pennsylvania was held June 2, eighteen women receiving the degree of Doctor of Medicine.——The thirty-fourth annual commencement of the Medico-Chirurgical College was held June 5, and seventy-five men received the degree of Doctor of Medicine.——The eighty-ninth annual commencement of Jefferson Medical College was held at the Academy of Music, June 6, when 147 men received the degree of Doctor of Medicine.

Personal.—Dr. Henry W. Rihl celebrated his 91st birthday anniversary at his home in Germantown, June 2.——Dr. S. W. Newmayer has been appointed assistant to the chief medical inspector of the Department of Health, to succeed Dr. Charles A. Groff, resigned.——Dr. James M. Anders has been appointed a member of the Board of Health of Philadelphia, to succeed Dr. Charles H. Andrus, Chestnut Hill.——Drs. William H. Walsh and Leonard D. Frescoln have qualified for the $4,000 post of resident physician of the Philadelphia General Hospital.

Alumnae Association Meeting.—The thirty-ninth annual meeting of the Alumnae Association of the Women's Medical College of Pennsylvania, was held June 2. Dr. Elizabeth L. Peck was elected president, Drs. Marie L. Bauer and Frances C. Vangaskin were elected vice-presidents, and the following officers were reelected: Dr. Jacobina S. Reddie, recording secretary; Dr. Mary Buchanan, corresponding secretary, and Dr. Ella C. Potter, treasurer. Announcement was made of a number of special gifts to the college, including a fellowship fund of $500 to be awarded annually for postgraduate work to a student showing special ability in teaching. The reception and banquet were held at the Bellevue Stratford in the evening.

Babies Emergency Bureau.—A central bureau has been established at City Hall by the Public Health Association, which affords advice, aid and directs personal relief to all mothers who wish to call on it. If the baby is sick, if it needs physician's attention, if a trained nurse's services are required, the mother has only to call up Electrical Bureau, 91, day or night and consult the child experts in charge. The office is in Room 714 of City Hall, and Miss Gertrude Rhoads is the executive secretary. Every nurse, every dispensary, every asylum, every hospital, every charity and welfare association in the city that has anything to do with babies, even clubs, churches, insurance companies have banded together in the Babies' Welfare Association, and place their resources at its command.

TENNESSEE

Hospital Opens.—The new Children's Hospital, on the grounds of the City Hospital, Memphis, which was recently built at a cost of $15,000, was formally opened for a public reception, May 25.

New Officers of State Board.—Dr. Rufus E. Fort, Nashville, was reelected president, and Dr. Andrew M. Gamble, Maryville, was elected vice-president of the board, which also elected Dr. Vincent A. Biggs, Martin, a member of the State Board of Embalmers.

Personal.—Dr. J. McChesney Hogshead has been appointed chief of staff of Erlanger Hospital, Chattanooga, succeeding Dr. John S. Dye.——Dr. Robert Mann, Memphis, who was stricken with appendicitis while operating for that condition in the Baptist Memorial Hospital recently, is making good progress toward recovery.

Tropical Dysentery.—Ten patients in three families at Erlanger, Chattanooga, suffered from a form of dysentery which was found after considerable investigation to be due to the bacillus of Shiga. This infection is unusual in this climate but is frequent in tropical countries and is fatal in from 7 to 20 per cent. of cases. The diagnosis was confirmed by experts.

New Officers.—East Tennessee Medical Association at Harriman, May 21 and 22: president, Dr. George P. Zirkle, Kingston; secretary-treasurer, Dr. Hiller P. Larimore, Chattanooga (reelected). The next semi-annual meeting will be held at Rogersville, and the annual meeting in Athens in May of next year.——Middle Tennessee Medical Association at Bellbuckle, May 22: president, Dr. Otey J. Porter, Columbia; secretary-treasurer, Dr. Roy W. Billington, Nashville.

VIRGINIA

State Sanatorium Completed.—The State Board of Health announces that the new infirmary building at Catawba has been completed and occupied, and that from now on the board will be able to admit suitable cases to the sanatorium without delay.

Northern Neck Physicians Meet.—At the semi-annual meeting of the Medical Association of the Northern Neck, held at Heathsville, May 28, Dr. Robert E. Booker, Lottsburg, was elected president; Dr. Stonewall Rice, Heathsville, vice-president; and Dr. Robert O. Lyell, Warsaw, secretary and treasurer.

Personal.—The address to the graduating class of the Medical College of Virginia was delivered by Dr. John A. Ferrall, secretary of the North Carolina State Medical Society, on "Health Work as a Career."——Dr. Southgate Leigh, Norfolk, has been appointed a member of the Virginia State Board of Medical Examiners, vice Dr. Herbert Old, removed to Philadelphia.——Dr. J. Allison Hodges, Richmond, delivered the address to the graduating class of the Louisburg, N. C., Female College, May 28. The subject of the address was "Conservation of Nerves."——Dr. A. S. Priddy, Lynchburg, president of the State Epileptic Colony, has been elected president of the National Association for the Care, Study and Treatment of Epilepsy.

The Problem of the Feeble-Minded.—Plans to investigate the feeble-minded in the State of Virginia, authorized by the last General Assembly, were discussed by the State Board of Charities and Corrections at its meeting, May 14. The legislative appropriation provides $3,000 for two years, and the board is directed fully to investigate, determine plans for remedy, and to report to the next General Assembly. The investigation will first deal with feeble mentality and the criminal population, to establish the relation between criminality and feeble-mindedness; it will then turn on feeble-mindedness in the community, and will finally take up the solution of the problem either by segregation or by confinement in institutions.

GENERAL NEWS

Pennsylvania Alumni Smoker.—The Society of the Alumni of the Medical Department of the University of Pennsylvania announces that the smoker will be held in the Rathskeller of the Hotel Alamac, Atlantic City, on the evening of June 23.

Indian Service Physicians' Conference.—The Commissioners of the Indian Service of the Department of the Interior have called a conference of physicians in the Indian Service. It will be held at the Lapwai (Idaho) Indian Sanatorium, June 23-25, and disease conditions among Indians will be discussed.

Clinical Day for Orthopedists.—Clinical Day for the twenty-eighth annual meeting of the American Orthopedic Association will be held in Philadelphia, June 17, at the hospital of the University of Pennsylvania. Clinics will be given in the morning and afternoon, luncheon will be served at Houston Hall, and in the evening there will be a boatride on the Delaware River and supper at the Yacht Club.

Leper in Washington.—John R. Early, about whose status as a leper medical experts have disagreed for five years, and who escaped from the Diamond Head Leper Station near Port Townsend, Wash., May 18, was discovered at a fashionable hotel in Washington, June 2, and was returned to his old place of isolation near the city limits. The federal health authorities have asked the Honolulu Board of Health for permission to send Early to Molokai.

New England Alumni of Jefferson Medical College Meet.—The New England Association of Jefferson Medical College Alumni held its annual meeting in Boston, May 28, and elected the following officers: president, Dr. Patrick F. Gahan, Medford, Mass.; vice-president, Dr. Thomas J. Fitzmaurice, Bangor, Me.; secretary, Dr. Wallace P. MacCallum, Boston; and treasurer, Dr. Frank I. Payne, Westerly, R. I. It was voted to hold the next meeting in Providence.

Virginia and District Doctors Meet.—The annual meeting of the Medical Society of Northern Virginia and the District of Columbia was held in Manassas, Va., May 20. The following officers were elected: president, Dr. William P. Carr, Washington; vice-presidents, Drs. John D. Thomas, Washington, and William F. Merchant, Manassas; recording secretary, Dr. Thomas A. Groover, Washington; corresponding secretary, Dr. Joseph D. Rogers, Washington; and treasurer, Dr. William I. Robey, Herndon.

Glanders Vaccine not Effective.—As a result of extensive experiments with horses and other animals the experts of the Bureau of Animal Industry, Department of Agriculture, have reached the conclusion that mallein is not effective in the treatment of glanders. Its only value is as a diagnostic agent. Efforts to immunize animals with glanders vaccine were unsuccessful, and it is believed that the only way of eradicating glanders is to eliminate all animals showing signs of the disease, as has been the practice heretofore.

Railway Surgeons Meeting.—At the meeting of the Pennsylvania Railway Surgeons' Association, Lines East and West, at Atlantic City, June 19 and 20, one of the chief features of the meeting will be an illustrated address by Mr. T. H. Carrow, representative of Superintendent Newbern of the Insurance Department, on the "Preventative Function of the Company Surgeon in Railway Safety," based on the records of accident statistics of the Olean yards as compared with the Buffalo and other railway yards of similar size and type.

Academy of Medicine Meeting.—The thirty-ninth annual meeting of the American Academy of Medicine will be held in Atlantic City, June 19-22, under the presidency of Dr. John L. Heffron, Syracuse, N. Y. Chief among the topics for discussion will be "The Practice of Medicine and Industries, Considered Under the Heads of Menace to Health and Remediable and Preventive Measures." The president's address will be on "Modern Medicine and Social Problems," and the annual address by Oscar Riddle, Ph.D., of the Carnegie Institute, is to be on "Biologic Basis and Experimental Control of Sex."

Army Medical School Graduation.—The graduation exercises of the class of 1914 of the Army Medical School were held June 1, when a class of seventeen was graduated. An address was delivered by Lieut. Henry C. Coe, New York City, M.R.C., U. S. Army, and the diplomas were presented by Surgeon-General William C. Gorgas. The Hoff Memorial Medal was presented to Lieut. Charles L. Gandy, M.R.C., U. S. Army, by Col. John Van R. Hoff, M.R.C., U. S. Army, and the Sternberg Medal was presented to Lieut. Alexander W. Williams, M.R.C., U. S. Army by Lieut. Richard Slee, M.R.C., U. S. Army, Swiftwater, Pa.

Annual Meeting of Maryland Alumni.—The meeting of the Alumni Association of the University of Maryland School of Medicine was held May 30. The following officers were elected: president, Dr. James T. Jarrett, Portsmouth, Arthur M. Shipley, Baltimore, and J. Charles MacGill, Catonsville; recording secretary, Dr. Albert H. Carroll, Baltimore; assistant recording secretary, Dr. Walter F. Sowers, Baltimore; corresponding secretary, Dr. Howard W. Jones, Baltimore, and treasurer, Dr. John Houff, Baltimore. The address of the evening was made by Rev. H. M. Lichtliter on "Some By-Products of Medical Science."

Tropical Medical Men Meet.—The eleventh annual meeting of the American Society of Tropical Medicine was held at Harvard Medical School, Boston, May 29 and 30. The following officers were elected: president, Capt. Charles F. Craig, M.C., U. S. Army; vice-presidents, Dr. Milton J. Rosenau, Boston, and Maj. Bailey K. Ashford, M.C., U. S. Army; secretary, Dr. John M. Swan, Rochester, N. Y.; assistant-secretary, Dr. Allen J. Smith, Philadelphia; delegate to the Executive Council of the Congress of American Physicians and Surgeons, Surg.-Gen. William C. Gorgas, M.C., U. S. Army; alternate, Capt. Joseph F. Siler, M.C., U. S. Army. The next meeting will probably be held in San Francisco.

Civil Service Examinations.—The United States Civil Service Commission announces an open competitive examination for assistant epidemiologist, for men only. The salaries of this position range from $2,000 to $2,500. The duties are to conduct laboratory studies of diseases, to determine the cause of epidemics and to recommend measures to control the diseases. Applicants must be between 23 and 40 years of age, and must have had an education equivalent to that of a medical school or college of recognized standing, at least three years' experience in epidemiologic work under federal, state, or local authorities, and be experienced in laboratory technic, especially in regard to typhoid fever. Application should be made to the United Civil Service Commission, Washington, D. C., and applicant should ask for form 304, giving the exact title, of the examination required, namely, "Assistant Epidemiologist, Male ($2,000-$2,500)."

The United States Civil Service Commission announces an open competitive examination for bacteriologist, for men only, to be held July 8, to fill vacancies. The salaries range from $1,200 to $2,000, and the positions are in the Bureau of Chemistry, Department of Agriculture. The applicant must be between 21 and 40 years of age, and must have an education equivalent to a Bachelor's degree or the degree of M.D., from a college of recognized standing, and must have had at least two years' training in bacteriology. Persons who desire to take the examinations should apply to the United States Civil Service Commission, Washington, D. C., giving the exact title of the examination desired, namely: "Bacteriologist (Male)."

Bequests and Donations.—The following bequests and donations have recently been announced:

Foundling Hospital and St. Vincent's Hospital, New York City, each $2,160 as residuary legatees of the estate of Miss Mary Guerin.

House of St. Giles the Cripple and Brooklyn Eye and Ear Hospital, each $2,500, by the will of Carl H. De Silver.

Home for Destitute Crippled Children and Foundlings' Home, Chicago, each $10,000, by the will of Henry M. Hooker.

Associated Jewish Charities, Chicago, $5,000; Michael Reese Hospital, $2,000; Home for Destitute Crippled Children, $1,000, by the will of Nathan Friend.

Methodist Hospital, Philadelphia, Pottsville, Pa., Hospital, each $50,000; Bryn Mawr, Pa., Hospital, $5,000; Institution for the Deaf and Dumb, Mt. Airy, Polyclinic Hospital and College for Graduates in Medicine, Philadelphia, Epileptic Hospital, Christ Church Hospital, Philadelphia Lying-In Hospital and Training School, Seaside Home for Invalid Women, Atlantic City, N. J., Children's Seashore House, Atlantic City, N. J., Women's Medical College, Rush Hospital for Consumption, German Hospital, American Oconologic Hospital, Chestnut Hill Hospital, each $10,000; for an endowment of a scholarship at the University of Pennsylvania, St. Christopher's Hospital for Children, Howard Hospital, Infirmary for Incurables, Kensington Hospital, Friends' Asylum for the Insane, Frankford Street, St. Agnes' Hospital, West Philadelphia Hospital, Woman's Hospital and Dispensary, Philadelphia Home for Incurables, Philadelphia College of Physicians, Home of the Merciful Savior for Crippled Children, Philadelphia Branch of the School for the Feeble-Minded in Memory of Dr. Jacob Mendes Da Costa, Orthopedic Hospital, and Episcopal Hospital, each $5,000 by the will of Miss Elizabeth Swift Shippen; one-fifth of the residuary estate to the Pottsville, Pa., Hospital and Eighth Street Branch of the Pennsylvania Hospital for Cases Thought Incurable.

Adirondack Cottage Sanitarium, one-twelfth; Presbyterian Hospital, one-twelfth; St. Luke's Hospital, one-thirtieth; Charity Organization Society, three-twentieths; Manhattan Eye, Ear and Throat Infirmary, one-thirtieth; Society for the Relief of the Destitute Blind, one-thirtieth; Home for Incurables, one-tenth; State Charitable Aid Association, one-thirtieth, from the estate of William Hale Penfold, appraised at $995,000, after the death of Edmund Penfold.

Dr. Edward L. Trudeau, Saranac Lake, N. Y., $10,000, by the will of William Hale Penfold.

Stanford University Medical School, $10,000, by the will of Charles G. Latrop.

Deaths Proved Not Due to Antityphoid Vaccine.—Dr. S. S. Goldwater, Commissioner of Health of New York City, has rendered a great service to medicine and the public by causing an investigation of deaths and severe illness reported in the newspapers as due to antityphoid vaccine. According to newspaper statements, Clarence E. Pantzer, a private in the National Guard of Brooklyn, died as a result of injection of antityphoid vaccine. The Army surgeons who made the inoculation claimed that the death was not due to this cause. After a protracted dispute, in which Health Commissioner Goldwater recalled a burial permit previously issued, an autopsy was performed under the direction of the coroner, which showed that death was caused by malignant endocarditis. No evidence of typhoid fever could be found in the post-mortem examination. In another instance, two children were inoculated with the vaccine, at the request of their father who was at the time sick with typhoid. Marked and severe symptoms later occurred, which were immediately credited to the injection of the vaccine, and the statement was made that the children were suffering from blood poisoning. Thus, the following statement appeared in a number of newspapers simultaneously:

> While militiamen in many states of the west are being immunized against typhoid fever, two children in New York are near death as a result of typhoid serum injections. Their mother, brother, and aunt are recovering from an attempt to immunize them.

In this instance, as well, Dr. Goldwater ordered a thorough investigation, and it has now been shown definitely that both children are suffering from typhoid contracted, without any doubt, prior to the administration of the vaccine. In one case, owing to the pressure of an accumulation of cerebrospinal fluid, the disease closely resembled the epidemic form of meningitis; thus confusing still further the symptoms and making very difficult the diagnosis. In speaking of these cases, Deputy Commissioner Emerson emphasized the fact that typhoid vaccinations were both harmless and efficacious. "According to the department's records most of the secondary or direct contact cases become infected while the physician is waiting for more definite symptoms in the original case. In the presence of any illness, even remotely suspected of being typhoid fever, prompt immunization of every member of the family is of great advantage. Those who develop the disease after immunization invariably show evidence of having contracted the infection before the immunizing injection."

FOREIGN

Personal.—Two suffragists, June 3, waylaid and attacked Dr. W. A. Foreward, deputy-governor of Holloway Gaol, London, in charge of the medical work at the prison.——Sir William Osler, regius professor of medicine at Oxford University, has been elected foreign associate of the Paris Academy of Medicine.

Deaths Abroad.—The following deaths have recently been announced from abroad: Sir Francis Henry Laking, M.D., Heidelberg, 1869; M.R.C.P., London, 1872; Grand Commander of the Victorian Order; Commander of the Bath; Apothecary to His Majesty's household; physician-in-ordinary and surgeon-apothecary to King George V, and to the Prince of Wales; died at his home in London, May 28, aged 67.——G. Antonelli, professor of anatomy at Naples.

Hygiene and the Red Cross at the Swiss National Exhibition, Berne.—The Hygiene and Red Cross sections of the Swiss National Exhibition in Berne, which opened on May 15 and which will last until October 15 next, are of interest. The exhibition has been partly arranged by the Swiss hospitals. The Swiss Health Office shows its methods of testing food with a view to preventing adulteration and also its methods of inspecting slaughterhouses, and space is devoted to the work of the Red Cross and Ambulances Associations.

The period of the exhibition has also been chosen by a number of congresses and conferences, both national and international, as an opportune moment for a meeting. The Swiss Society of Neurology, for instance, called an International Congress of Neurology, Psychiatry and Psychology to be held at Berne from September 7 to 12 next. An organization committee and various international committees have been appointed.

CANADA

Hospital News.—Dr. Harry Morrell, Regina, has been appointed director of the pathologic laboratory of the Regina General Hospital, with Dr. Seymour Ross as assistant.——It is expected that the new Regina Isolation Hospital in connection with the General Hospital of that city, will be ready for the reception of patients on August 15.——The Regina General Hospital is building a nurses' home at a cost of $125,000.——A site of 230 acres has been acquired for the Saskatchewan sanatorium for tuberculosis at Ft. Qu'Appelle, and construction work on the buildings has been recommenced.

McGill University News.—At the recent meeting of the Board of Governors the resignations were accepted of Drs. Walton, Howard T. Barnes and R. H. Miller. Dean Walton has accepted a position with the Egyptian Government at Cairo; Dr. Barnes will take up the duties of professor of physics in the new University of British Columbia; Dr. Miller will go to the Western University, London, Ontario.——Mr. G. R. Mines, M.A., has been appointed to the Joseph Morley Drake chair of physiology; Dr. Douglas McIntosh to be professor of physical chemistry; Dr. J. W. Tait to be assistant professor of psychology; Dr. F. M. G. Johnston, associate professor of chemistry; Dr. R. V. Krieble, assistant professor of chemistry. In the faculty of medicine, Dr. L. J. Rhea has been appointed associate professor of pathology; Dr. C. K. Russel, lecturer in neurology; Dr. A. Freedman, assistant in anatomy; Dr. Maude E. Abbott, lecturer in pathology; Drs. H. B. Cushing and C. A. Peters, lecturers in medicine and clinical medicine; Dr. E. M. von Eberts, lecturer in surgery and clinical surgery; Dr. H. C. Burgess, lecturer in gynecology. Dr. J. J. Ower was appointed to the fellowship in pathology maintained by Dr. James Douglas, New York, one of the governors of the university, and Dr. R. H. Malone to the studentship in the same subject, also maintained by Dr. Douglas.

LONDON LETTER

London, May 22, 1914.

Imperial Health Conference

The Imperial Health Conference, organized by the Victoria League for the promotion of knowledge of house and town planning and the care of child life throughout the empire, was opened at the Imperial Institute by Mr. Lewis Harcourt, secretary of state for the colonies. About 300 delegates, representing the governments of the various colonies, as well as local authorities and organizations throughout the United Kingdom, were present. In his address Mr. Harcourt said that the great difficulty which confronted the work of housing reform in this country was the congestion of population in the hearts of the towns. The last word in town-planning rested with Australia, which was entering on the building of a federal capital. It was their boast that during the past nine years the rates of West African invalidity had been reduced from 56 to 25 per thousand. The conference adjourned for the purpose of attending the opening of the Victoria League health exhibition, which was also held in the Imperial Institute. It embraced two classes of exhibits. One dealt with town planning, which was illustrated by plans and photographs of various garden city and housing schemes relating to the United Kingdom and many of the oversea dominions. The other section dealt with the welfare of children from babyhood to maturity, illustrated by exhibits relating to the treatment of children in all parts of the empire, in health and sickness, at work, at school, at play and asleep.

Royal Commission on Venereal Diseases

At the thirty-third meeting of the Royal Commission on Venereal Diseases, evidence was given by Sir Herbert Smalley, M.D., one of the commissioners of prisons. He said that it was his firm impression, and also that of many of the senior medical officers of prisons, that venereal diseases were less prevalent in prisons than thirty and even twenty years ago, and that the cases were less severe in character. He was inclined to think, however, that the later stages of syphilis affecting the circulatory and nervous systems were more prevalent. Under 2 per cent. of prisoners presented manifest symptoms of either gonorrhea or syphilis. The highest incidence occurred among prisoners committed from large towns and manufacturing or mining districts, and cases of venereal disease were disproportionately numerous in prisons receiving prisoners from seaport towns. About half of those suffering from venereal disease were still in an infectious condition when discharged. This problem might be attacked either by detention, notification or by the provision of facilities for treatment subsequent to discharge. The first alternative was of doubtful expediency, and any form of notification other than that which was made applicable to the whole community would be inadvisable. The idea of a prisoner being specially penalized or of his sentence being enhanced on account of venereal disease would, he thought, be strenuously resisted. He was not in favor of venereal disease being made notifiable generally throughout the community. The provision of facilities for treatment seemed to offer a more hopeful solution. Means should be provided throughout the country for treatment of venereal disease free of cost, readily accessible, and with attendance permissible in the evening so as not to interfere with the daily work of the patient. As far as possible these centers should be at general hospitals and dispensaries rather than at special hospitals or centers solely for the treatment of venereal diseases. If such centers were organized it would enable a prison doctor to give a discharged prisoner a ticket, the presentation of which at a center would secure the patient a continuance of treatment. The fact of the patient being recently discharged from prison should be a confidential matter and should be made known at the treatment center to as few persons as possible. In convict prisons out of 1,755 male convicts 299, or 17 per cent., showed signs of having had syphilis.

Government Report on Sleeping-Sickness

The report on sleeping-sickness has been issued by the Interdepartmental Committee, which has been investigating the part played by wild animals and the tsetse-fly in Africa in the spread of the disease and has been considering whether or not it is advisable to attempt the extermination of wild animals, either generally or in a special area, and whether or not any other measures should be taken to check the of Columbia was held in Manassas, Va., May 20. The following officers were elected: president, Dr. William P. Carr, Washington; vice-presidents, Drs. John D. Thomas, Washington, and William F. Merchant, Manassas; recording secretary, Dr. Thomas A. Groover, Washington; corresponding secretary, Dr. Joseph D. Rogers, Washington; and treasurer, Dr. William I. Robey, Herndon.

Glanders Vaccine not Effective.—As a result of extensive experiments with horses and other animals the experts of the Bureau of Animal Industry, Department of Agriculture, have reached the conclusion that mallein is not effective in the treatment of glanders. Its only value is as a diagnostic agent. Efforts to immunize animals with glanders vaccine were unsuccessful, and it is believed that the only way of eradicating glanders is to eliminate all animals showing signs of the disease, as has been the practice heretofore.

Railway Surgeons Meeting.—At the meeting of the Pennsylvania Railway Surgeons' Association, Lines East and West, at Atlantic City, June 19 and 20, one of the chief features of the meeting will be an illustrated address by Mr. T. H. Carrow, representative of Superintendent Newbern of the Insurance Department, on the "Preventative Function of the Company Surgeon in Railway Safety," based on the records of accident statistics of the Olean yards as compared with the Buffalo and other railway yards of similar size and type.

Academy of Medicine Meeting.—The thirty-ninth annual meeting of the American Academy of Medicine will be held in Atlantic City, June 19-22, under the presidency of Dr. John L. Heffron, Syracuse, N. Y. Chief among the topics for discussion will be "The Practice of Medicine and Industries, Considered Under the Heads of Menace to Health and Remediable and Preventive Measures." The president's address will be on "Modern Medicine and Social Problems," and the annual address by Oscar Riddle, Ph.D., of the Carnegie Institute, is to be on "Biologic Basis and Experimental Control of Sex."

Army Medical School Graduation.—The graduation exercises of the class of 1914 of the Army Medical School were held June 1, when a class of seventeen was graduated. An address was delivered by Lieut. Henry C. Coe, New York City, M.R.C., U. S. Army, and the diplomas were presented by Surgeon-General William C. Gorgas. The Hoff Memorial Medal was presented to Lieut. Charles L. Gandy, M.R.C., U. S. Army, by Col. John Van R. Hoff, M.R.C., U. S. Army, and the Sternberg Medal was presented to Lieut. Alexander W. Williams, M.R.C., U. S. Army by Lieut. Richard Slee, M.R.C., U. S. Army, Swiftwater, Pa.

Annual Meeting of Maryland Alumni.—The meeting of the Alumni Association of the University of Maryland School of Medicine was held May 30. The following officers were elected: president, Dr. James T. Jarrett, Portsmouth, Arthur M. Shipley, Baltimore, and J. Charles MacGill, Catonsville; recording secretary, Dr. Albert H. Carroll, Baltimore; assistant recording secretary, Dr. Walter F. Sowers, Baltimore; corresponding secretary, Dr. Howard W. Jones, Baltimore, and treasurer, Dr. John Houff, Baltimore. The address of the evening was made by Rev. H. M. Lichtliter on "Some By-Products of Medical Science."

Tropical Medical Men Meet.—The eleventh annual meeting of the American Society of Tropical Medicine was held at Harvard Medical School, Boston, May 29 and 30. The following officers were elected: president, Capt. Charles F. Craig, M.C., U. S. Army; vice-presidents, Dr. Milton J. Rosenau, Boston, and Maj. Bailey K. Ashford, M.C., U. S. Army; secretary, Dr. John M. Swan, Rochester, N. Y.; assistant-secretary, Dr. Allen J. Smith, Philadelphia; delegate to the Executive Council of the Congress of American Physicians and Surgeons, Surg.-Gen. William C. Gorgas, M.C., U. S. Army; alternate, Capt. Joseph F. Siler, M.C., U. S. Army. The next meeting will probably be held in San Francisco.

Civil Service Examinations.—The United States Civil Service Commission announces an open competitive examination for assistant epidemiologist, for men only. The salaries of this position range from $2,000 to $2,500. The duties are to conduct laboratory studies of diseases, to determine the cause of epidemics and to recommend measures to control the diseases. C., and applicant should ask for form 304, giving the exact title, of the examination required, namely, "Assistant Epidemiologist, Male ($2,000-$2,500)."

The United States Civil Service Commission announces an open competitive examination for bacteriologist, for men only, to be held July 8, to fill vacancies. The salaries range from $1,200 to $2,000, and the positions are in the Bureau of Chemistry, Department of Agriculture. The applicant must be between 21 and 40 years of age, and must have an education equivalent to a Bachelor's degree or the degree of M.D., from a college of recognized standing, and must have had at least two years' training in bacteriology. Persons who desire to take the examinations should apply to the United States Civil Service Commission, Washington, D. C., giving the exact title of the examination desired, namely: "Bacteriologist (Male)."

Bequests and Donations.—The following bequests and donations have recently been announced:

Foundling Hospital and St. Vincent's Hospital, New York City, each $2,160 as residuary legatees of the estate of Miss Mary Guerin.

House of St. Giles the Cripple and Brooklyn Eye and Ear Hospital, each $2,500, by the will of Carl H. De Silver.

Home for Destitute Crippled Children and Foundlings' Home, Chicago, each $10,000, by the will of Henry M. Hooker.

Associated Jewish Charities, Chicago, $5,000; Michael Reese Hospital, $2,000; Home for Destitute Crippled Children, $1,000, by the will of Nathan Friend.

Methodist Hospital, Philadelphia, Pottsville, Pa., Hospital, each $50,000; Bryn Mawr, Pa., Hospital, $5,000; Institution for the Deaf and Dumb, Mt. Airy, Polyclinic Hospital and College for Graduates in Medicine, Philadelphia, Epileptic Hospital, Christ Church Hospital, Philadelphia Lying-In Hospital and Training School, Seaside Home for Invalid Women, Atlantic City, N. J., Children's Seashore House, Atlantic City, N. J., Women's Medical College, Rush Hospital for Consumption, German Hospital, American Oconologic Hospital, Chestnut Hill Hospital, each $10,000; for an endowment of a scholarship at the University of Pennsylvania, St. Christopher's Hospital for Children, Howard Hospital, Infirmary for Incurables, Kensington Hospital, Friends' Asylum for the Insane, Frankford Street, St. Agnes' Hospital, West Philadelphia Hospital, Woman's Hospital and Dispensary, Philadelphia Home for Incurables, Philadelphia College of Physicians, Home of the Merciful Savior for Crippled Children, Philadelphia Branch of the School for the Feeble-Minded in Memory of Dr. Jacob Mendes Da Costa, Orthopedic Hospital, and Episcopal Hospital, each $5,000 by the will of Miss Elizabeth Swift Shippen; one-fifth of the residuary estate to the Pottsville, Pa., Hospital and Eighth Street Branch of the Pennsylvania Hospital for Cases Thought Incurable.

Adirondack Cottage Sanitarium, one-twelfth; Presbyterian Hospital, one-twelfth; St. Luke's Hospital, one-thirtieth; Charity Organization Society, three-twentieths; Manhattan Eye, Ear and Throat Infirmary, one-thirtieth; Society for the Relief of the Destitute Blind, one-thirtieth; Home for Incurables, one-tenth; State Charitable Aid Association, one-thirtieth, from the estate of William Hale Penfold, appraised at $995,000, after the death of Edmund Penfold.

Dr. Edward L. Trudeau, Saranac Lake, N. Y., $10,000, by the will of William Hale Penfold.

Stanford University Medical School, $10,000, by the will of Charles G. Latrop.

Deaths Proved Not Due to Antityphoid Vaccine.—Dr. S. S. Goldwater, Commissioner of Health of New York City, has rendered a great service to medicine and the public by causing an investigation of deaths and severe illness reported in the newspapers as due to antityphoid vaccine. According to newspaper statements, Clarence E. Pantzer, a private in the National Guard of Brooklyn, died as a result of injection of antityphoid vaccine. The Army surgeons who made the inoculation claimed that the death was not due to this cause. After a protracted dispute, in which Health Commissioner Goldwater recalled a burial permit previously issued, an autopsy was performed under the direction of the coroner, which showed that death was caused by malignant endocarditis. No evidence of typhoid fever could be found in the post-mortem examination. In another instance, two children were inoculated with the vaccine, at the request of their father who was at the time sick with typhoid. Marked and severe symptoms later occurred, which were immediately credited to the injection of the vaccine, and the statement was made that the children were suffering from blood poisoning. Thus, the following statement appeared in a number of newspapers simultaneously:

> While militiamen in many states of the west are being immunized against typhoid fever, two children in New York are near death as a result of typhoid serum injections. Their mother, brother, and aunt are recovering from an attempt to immunize them.

In this instance, as well, Dr. Goldwater ordered a thorough investigation, and it has now been shown definitely that both children are suffering from typhoid contracted, without any doubt, prior to the administration of the vaccine. In one case, owing to the pressure of an accumulation of cerebrospinal fluid, the disease closely resembled the epidemic form of meningitis; thus confusing still further the symptoms and making very difficult the diagnosis. In speaking of these cases, Deputy Commissioner Emerson emphasized the fact that typhoid vaccinations were both harmless and efficacious. "According to the department's records most of the secondary or direct contact cases become infected while the physician is waiting for more definite symptoms in the original case. In the presence of any illness, even remotely suspected of being typhoid fever, prompt immunization of every member of the family is of great advantage. Those who develop the disease after immunization invariably show evidence of having contracted the infection before the immunizing injection."

FOREIGN

Personal.—Two suffragists, June 3, waylaid and attacked Dr. W. A. Foreward, deputy-governor of Holloway Gaol, London, in charge of the medical work at the prison.——Sir William Osler, regius professor of medicine at Oxford University, has been elected foreign associate of the Paris Academy of Medicine.

Deaths Abroad.—The following deaths have recently been announced from abroad: Sir Francis Henry Laking, M.D., Heidelberg, 1869; M.R.C.P., London, 1872; Grand Commander of the Victorian Order; Commander of the Bath; Apothecary to His Majesty's household; physician-in-ordinary and surgeon-apothecary to King George V, and to the Prince of Wales; died at his home in London, May 28, aged 67.——G. Antonelli, professor of anatomy at Naples.

Hygiene and the Red Cross at the Swiss National Exhibition, Berne.—The Hygiene and Red Cross sections of the Swiss National Exhibition in Berne, which opened on May 15 and which will last until October 15 next, are of interest. The exhibition has been partly arranged by the Swiss hospitals. The Swiss Health Office shows its methods of testing food with a view to preventing adulteration and also its methods of inspecting slaughterhouses, and space is devoted to the work of the Red Cross and Ambulances Associations.

The period of the exhibition has also been chosen by a number of congresses and conferences, both national and international, as an opportune moment for a meeting. The Swiss Society of Neurology, for instance, called an International Congress of Neurology, Psychiatry and Psychology to be held at Berne from September 7 to 12 next. An organization committee and various international committees have been appointed.

CANADA

Hospital News.—Dr. Harry Morrell, Regina, has been appointed director of the pathologic laboratory of the Regina General Hospital, with Dr. Seymour Ross as assistant.——It is expected that the new Regina Isolation Hospital in connection with the General Hospital of that city, will be ready for the reception of patients on August 15.——The Regina General Hospital is building a nurses' home at a cost of $125,000.——A site of 230 acres has been acquired for the Saskatchewan sanatorium for tuberculosis at Ft. Qu'Appelle, and construction work on the buildings has been recommenced.

McGill University News.—At the recent meeting of the Board of Governors the resignations were accepted of Drs. Walton, Howard T. Barnes and R. H. Miller. Dean Walton has accepted a position with the Egyptian Government at Cairo; Dr. Barnes will take up the duties of professor of physics in the new University of British Columbia; Dr. Miller will go to the Western University, London, Ontario.——Mr. G. R. Mines, M.A., has been appointed to the Joseph Morley Drake chair of physiology; Dr. Douglas McIntosh to be professor of physical chemistry; Dr. J. W. Tait to be assistant professor of psychology; Dr. F. M. G. Johnston, associate professor of chemistry; Dr. R. V. Krieble, assistant professor of chemistry. In the faculty of medicine, Dr. L. J. Rhea has been appointed associate professor of pathology; Dr. C. K. Russel, lecturer in neurology; Dr. A. Freedman, assistant in anatomy; Dr. Maude E. Abbott, lecturer in pathology; Drs. H. B. Cushing and C. A. Peters, lecturers in medicine and clinical medicine; Dr. E. M. von Eberts, lecturer in surgery and clinical surgery; Dr. H. C. Burgess, lecturer in gynecology. Dr. J. J. Ower was appointed to the fellowship in pathology maintained by Dr. James Douglas, New York, one of the governors of the university, and Dr. R. H. Malone to the studentship in the same subject, also maintained by Dr. Douglas.

LONDON LETTER

London, May 22, 1914.

Imperial Health Conference

The Imperial Health Conference, organized by the Victoria League for the promotion of knowledge of house and town planning and the care of child life throughout the empire, was opened at the Imperial Institute by Mr. Lewis Harcourt, secretary of state for the colonies. About 300 delegates, representing the governments of the various colonies, as well as local authorities and organizations throughout the United Kingdom, were present. In his address Mr. Harcourt said that the great difficulty which confronted the work of housing reform in this country was the congestion of population in the hearts of the towns. The last word in town-planning rested with Australia, which was entering on the building of a federal capital. It was their boast that during the past nine years the rates of West African invalidity had been reduced from 56 to 25 per thousand. The conference adjourned for the purpose of attending the opening of the Victoria League health exhibition, which was also held in the Imperial Institute. It embraced two classes of exhibits. One dealt with town planning, which was illustrated by plans and photographs of various garden city and housing schemes relating to the United Kingdom and many of the oversea dominions. The other section dealt with the welfare of children from babyhood to maturity, illustrated by exhibits relating to the treatment of children in all parts of the empire, in health and sickness, at work, at school, at play and asleep.

Royal Commission on Venereal Diseases

At the thirty-third meeting of the Royal Commission on Venereal Diseases, evidence was given by Sir Herbert Smalley, M.D., one of the commissioners of prisons. He said that it was his firm impression, and also that of many of the senior medical officers of prisons, that venereal diseases were less prevalent in prisons than thirty and even twenty years ago, and that the cases were less severe in character. He was inclined to think, however, that the later stages of syphilis affecting the circulatory and nervous systems were more prevalent. Under 2 per cent. of prisoners presented manifest symptoms of either gonorrhea or syphilis. The highest incidence occurred among prisoners committed from large towns and manufacturing or mining districts, and cases of venereal disease were disproportionately numerous in prisons receiving prisoners from seaport towns. About half of those suffering from venereal disease were still in an infectious condition when discharged. This problem might be attacked either by detention, notification or by the provision of facilities for treatment subsequent to discharge. The first alternative was of doubtful expediency, and any form of notification other than that which was made applicable to the whole community would be inadvisable. The idea of a prisoner being specially penalized or of his sentence being enhanced on account of venereal disease would, he thought, be strenuously resisted. He was not in favor of venereal disease being made notifiable generally throughout the community. The provision of facilities for treatment seemed to offer a more hopeful solution. Means should be provided throughout the country for treatment of venereal disease free of cost, readily accessible, and with attendance permissible in the evening so as not to interfere with the daily work of the patient. As far as possible these centers should be at general hospitals and dispensaries rather than at special hospitals or centers solely for the treatment of venereal diseases. If such centers were organized it would enable a prison doctor to give a discharged prisoner a ticket, the presentation of which at a center would secure the patient a continuance of treatment. The fact of the patient being recently discharged from prison should be a confidential matter and should be made known at the treatment center to as few persons as possible. In convict prisons out of 1,755 male convicts 299, or 17 per cent., showed signs of having had syphilis.

Government Report on Sleeping-Sickness

The report on sleeping-sickness has been issued by the Interdepartmental Committee, which has been investigating the part played by wild animals and the tsetse-fly in Africa in the spread of the disease and has been considering whether or not it is advisable to attempt the extermination of wild animals, either generally or in a special area, and whether or not any other measures should be taken to check the disease. The committee finds that there are two distinct forms of sleeping-sickness. There is the Uganda form, which appears to be a new disease, and was first recognized in 1901. It is violently epidemic, and is estimated to have caused 200,000 deaths between 1898 and 1906. On the other hand, there is the sleeping-sickness of Nyasaland and Rhodesia. This has been recognized as a distinct form of the disease only since 1908. It is almost certainly not epidemic. The total number of cases which a vigorous search has been able to discover is 153 in Nyasaland and 107 in Rhodesia from 1908 to 1914. It is said that the natives recognize this as an old disease. Though much less widespread than the Uganda disease, the sleeping-sickness of Nyasaland and Rhodesia is far more deadly. Death usually results in from three to six months after the appearance of the symptoms. Hitherto no treatment has been successful, and the disease may be regarded as almost invariably fatal. The Uganda form, on the other hand, is much more prolonged. Even untreated cases usually last from eighteen months to two years. If the patient is treated at an early stage life is often prolonged for years, and there are many cases of apparent recovery. The tsetse-fly has in each case proved to be the carrier of the disease; but it has also been proved that Uganda sleeping-sickness is caused by a different species of the tsetse-fly from that which carries the Rhodesian or Nyasaland form. The *Glossina palpalis,* which carries the Uganda disease, never goes far from water, and is altogether unknown in those parts of Nyasaland and Rhodesia where the other form of the disease occurs. It is now proved almost beyond doubt that the carrier in this case is *Glossina morsitans.* Its distribution is capricious and it seems to be independent of water. Its migrations are not understood, and its length of flight in search of food is unknown. As to the part played by wild animals in the distribution of sleeping-sickness, there appears to be little doubt that in the case of the Uganda form it is of minor importance as compared with that played by man himself as a reservoir from which the fly derives the infection. In the case of the Rhodesian or Nyasaland form there is much disagreement between the authorities, and the committee comes to the conclusion that the evidence is conflicting as to whether the wild animals which are a reservoir of the disease affecting domestic stock are a danger to man.

Tuberculosis in London

The London County Council has for some time been preparing a scheme for dealing with tuberculosis in the metropolis. This has now been completed and adopted. There will be a complete network of tuberculosis dispensaries at which treatment will be provided by the local sanitary authorities. For their upkeep the council will contribute so far as uninsured persons are concerned grants not exceeding 50 per cent. (provision for insured tuberculous persons has been made under the national insurance act, as reported in previous letters to The Journal). The dispensaries will be linked up with the hospitals. Arrangements will be made for residential treatment both in hospitals and sanatoriums. An advisory board representing hospitals, dispensaries and sanatoriums will assist in insuring some uniformity of standard in the selection of patients. Recommendations for residential treatment will be received from local medical officers of health. If, however, there appears to be any doubt as to the suitability of the case, it will be submitted to a rota of physicians to be selected by the advisory board. When a patient leaves the residential institution to which he has been sent by the council, arrangements will be made for the local dispensary or other suitable agency to continue his treatment. As a condition of receiving residential treatment, the patient undertakes to remain under medical supervision on his discharge. The committee is of opinion that by the end of the current financial year 160 beds will be required in hospitals and 240 beds in sanatoriums for adults, and 150 beds in residential institutions for children. The London Insurance Committee has obtained the accommodation which it requires at a price not exceeding $7.50 a week for each bed, and it will be possible for the council to obtain beds at ten hospitals and four sanatoriums on these conditions. Many more beds, however, will be necessary and the Asylums Board is to be asked to provide 150 beds. In the case of children the weekly charge for each bed should not exceed $5. The cost of the scheme for the present financial year is put at $144,605, toward which the government would contribute $61,250, and at $200,000 for 1915-1916, to which the government would contribute $100,000.

PARIS LETTER

Paris, May 22, 1914.

Personal

The Académie de médecine, at its session May 19, elected Charles Eduard Hédon, professor of physiology at the Faculté de médecine of Montpellier, and Charles Nicolle, director of the Pasteur Institute of Tunis, as national correspondents. Dr. Hédon is known especially for his experimental research work in pancreatic diabetes and has published a "Précis de physiologie." Dr. Charles Nicolle last year, in collaboration with Dr. Blaizot, introduced an atoxic antigonococcic vaccine (The Journal, Nov. 15, 1913, p. 1825).

Dr. Bosc, professor of pathologic anatomy at the Faculté de médecine de Montpellier, has just been appointed professor of pathology and general therapeutics at that school.

Dr. Etienne, professor of general and internal pathology at the Faculté de médecine de Nancy, has just been appointed professor of medical clinics at that school.

Physicians Elected Deputies

Fifty-five physicians have just been elected deputies, the same number as in 1910. Of these, thirty-seven were re-elected. It is an interesting fact that the three deputies from the department of Tarn-et-Garonne are all physicians.

The Plague at Senegal

The governor general of French West Africa has notified the Minister of the Colonies that seven cases of plague were reported, May 13, in a native village at some distance from Dakar. No new case has since developed.

General Anaphylaxis

Anaphylaxis has been conceded, hitherto, to be specific, in the sense that the substance used to produce anaphylactic shock must be identical with the sensitizing substance. Such a narrow specificity has been observed in certain cases that an animal which had been sensitized with goat's milk did not react to cow's milk, and that a guinea-pig which had been inoculated with rabbit-serum did not react to horse-serum, and vice versa. It appears from a series of experiments which Prof. Charles Richet has just reported to the Académie des Sciences that anaphylaxis need not be specific; animals which had been given non-fatal and (in appearance, at least) innocuous doses of phosphorus showed themselves susceptible to chloroform, just as animals did which had been chloroformed a month before. Richet concludes that, besides the specific anaphylaxis, a general anaphylaxis exists which is derived from indirect anaphylaxis (The Journal, Feb. 28, 1914, p. 711). The organism may, therefore, through one poison, be sensitized to quite different poisons.

Surgery for Diabetics

At the session of the Académie de médecine, May 19, Dr. Marcel Labbé, *agrégé* professor at the Faculté de médecine de Paris showed that the danger in operations on diabetics could be traced to two principal causes: hyperglycemia and acidosis, without considering vascular lesions which do not properly belong to diabetes. Hyperglycemia favors suppuration, but is far from being fatal in aseptic operations. It is well to combat hyperglycemia by a diet before operation.

Labbé deduces the following practical rules: Only imperative operations should be performed on diabetics; by preliminary treatment, glycemia, and acidosis should be reduced; a mixed diet of carbohydrates may be employed in the case of non-emaciated diabetics; a diet of dried vegetables, oats, or milk, with an alkaline treatment, may be given diabetics with acidosis. Before the operation 40 gm. of sodium bicarbonate should be administered. For the anesthetic the preference should be given to local or general anesthesia by ethyl chlorid. After the operation large doses of sodium bicarbonate should be administered orally or subcutaneously; then, when able to take food, the patient should be given vegetables, and oat or milk broths.

Refrigeration in the Hospitals of Paris

Dr. Lortat-Jacob has just reported the results of his inquiry into the use of refrigeration in the hospitals of Paris. With the exception of the Cochin hospital, the Hôpital de la Pitié and the military hospital at Val-de-Grâce, all the hospitals of Paris lack refrigeration facilities for the preservation of provisions and bodies. During the summer, more than 1,000 quarts of milk are lost each day in certain hospitals of Paris for lack of a suitable refrigerating plant.

BUDAPEST LETTER

Budapest, May 11, 1914.

Increase of Length of Life of Hungarian Women

The detailed statistical results of the last census, published at the end of last month, have been discussed by various medical men from different points of view. A noted gynecologist has examined the data available for comparing the duration of life between men and women, and concludes that women live longer than men. The average lifetime of the Hungarian women, according to the census taken in 1880, was 42.5 years, but according to the last census it is now 51 years. In some parts of Hungary the improvement is still greater. For instance, in the Székely district in Transsylvania the average is 59.2 years. According to this gynecologist the longevity of women is due to the fact that women work less than men. The data of the present census show that there are fewer hysteric and nervous women than in former years. Insanity has also decreased slightly. These favorable results are for the most part due to the general prosperity of the country. Wages in Hungary have been almost doubled during the last ten or twenty years by the increase in agriculture, trade and manufacturing.

Near-Sightedness in Schoolchildren

Dr. Bogdan, in his account of the examination of two hundred text-books from a sanitary point of view, draws particular attention to the fact, already established by many prominent investigators, that near-sightedness in children either originates or develops in connection with the schoolroom. The chief cause is the too prolonged reading, writing and drawing in which visual accommodation, as well as convergence, is greatly fatigued. Undue strain of the muscles of accommodation causes an active hyperemia; the venous circulation is hindered, there is an increase in the intra-ocular pressure and the sclerotic is gradually stretched. Too strong convergence works even greater harm. It is, of course, understood that in some children near-sightedness is hereditary, and as a result, they become affected more quickly than their healthier comrades. In addition, near-sightedness may be the result of insufficient light and improper equipment in desks and other school furniture.

Dr. Bogdan insists that the paper used in the text-books should not have a glossy surface. Under artificial light a glossy surface causes improper focusing of the eye and necessitates frequent changes in the position of the book as well as of the head. The paper should be thick enough to prevent the printing on one page from penetrating to another. A few authorities have recommended yellow paper, but the majority favor white paper, which gives a better contrast between the printed matter and the background.

Effects of Tobacco-Smoking

In a recent meeting of the Medical Society, Dr. Pekanovits read a paper on this subject. He stated that tobacco-smoke contained nicotanin, collidin and other pyridin derivatives, such as acids, resins, carbon dioxid, hydrocyanic acid and ammoniacal salts, as well as the nicotin. Two drops of nicotin placed on a dog's tongue produced great weakness, convulsions and death in less than a minute; eight drops were sufficient to kill a horse. Tobacco contained from 2 to 8 per cent. nicotin, and M. le Bon, a French investigator, had determined that although this was changed in smoking, still it was converted into other pyridin products, which were just as poisonous. Dr. Pekanovits found that the bodies did not condense to any appreciable extent in the mouth, and were for the most part exhaled, so that the physiologic effect of ordinary smoking was nil. Susceptible persons, however, might be affected by breathing the air in which there was much tobacco-smoke.

The action of nicotin has been shown by the investigations of Petit to be intermediate between that of bromids and that of digitalis. It soothes the nervous system, but causes a powerful and rapid contraction of the vessels and a rise in blood-pressure. One of its best-known dangers is angina pectoris, caused, perhaps, by the severe contractions of the coronary arteries. Prolonged use induces the development of arteriosclerosis. Tobacco is a "habit-drug" like opium, cocain and alcohol; its devotee, although he is aware of its harm, loses the force of will necessary to break the habit. Tobacco-smoke has apparently no bactericidal action on any micro-organisms present in the lungs. One of the first effects of an overdose is nausea. Prolonged smoking is a distinct factor in the production of digestive troubles.

Marriages

Frank J. Erdlitz, M.D., Johannesburg, Mich., to Miss Matilda La Rivere of Manistee, Mich., at Grayling, Mich., May 20.

Louis Raymond Burnett, M.D., Cambridge, Mass., to Miss Isabel Knowlton Thomas, Milton, Mass., recently.

Gaylord Eugene Pitts, M.D., Mount Horeb, Wis., to Miss Agnes Helene Dahle of Minneapolis, May 28.

William A. Gardner, M.D., Cincinnati, to Miss Bertha Kleinknecht, at Middletown, Ohio, April 14.

William L. Munroe, M.D., Pittsburgh, Pa., to Miss Frances Rudd Eno of Pine Plains, N. Y., June 1.

Ralph Frank Luse, M.D., Comanche, Iowa, to Miss Pearl Minear of Council Bluffs, Iowa, May 26.

Charles Henry Schmidt, M.D., Chicago, to Miss Effie Olson of Melrose Park, Ill., May 28.

Herman Renner, M.D., Chattanooga, Tenn., to Miss Marie Kinny of New York City, recently.

Worth Clark, M.D., to Miss Florence Cunningham, at Charleston, W. Va., May 14.

Arter W. Deal, M.D., to Miss Gladys Smith, both of Lewistown, Mont., May 25.

Deaths

Emil Gruening, M.D. College of Physicians and Surgeons in the City of New York, 1867; a veteran of the Civil War; and a pioneer ophthalmologist and otologist of New York City; died at his home, May 30, from cerebral endarteritis, aged 71. Dr. Gruening was appointed assistant surgeon to the New York Ophthalmic and Oral Institute in 1871; ophthalmic surgeon to Mt. Sinai Hospital in 1879, and to the German Hospital in 1880. At the time of his death he was consulting ophthalmic and oral surgeon to Mt. Sinai Hospital; consulting ophthalmic surgeon to the German Hospital and New York Eye and Ear Infirmary; and consulting surgeon to the New York Infirmary for Women and Children. He had served as president of the American Ophthalmologic Society, American Otological Society and Society for Relief of Widows and Orphans of Medical Men; he was also a member of the American Laryngological, Rhinological and Otological Society, and many other scientific bodies. Among his most notable achievements were the development of the mastoid operation, and his warning regarding the danger of blindness from the use of wood alcohol. He was a voluminous contributor to the literature of his specialty; and was the author of the chapter on "Diseases of the Eye" in Norris and Oliver's encyclopedic work.

Samuel Caldwell Benedict, M.D. Miami Medical College, Cincinnati, 1880; of Athens, Ga.; a member of the Medical Association of Georgia, and its president in 1900; acting assistant surgeon, U. S. Army, in 1880 and 1881; professor of medical jurisprudence in the law school of the University of Georgia, Augusta, since 1883, and professor of materia medica in the school of Pharmacy; local surgeon of the Seaboard Air Line, Central Railroad of Georgia, Gainesville Midland Railroad and Georgia Railroad; president of the Association of Surgeons of the Central Railroad of Georgia in 1903; and of the Association of Seaboard Air Line Surgeons in 1911; a member of the State Board of Health of Georgia, and its president in 1911; died in a sanatorium in Macon, Ga., June 1, aged 58.

Charles Hicklen Preston, M.D. University of Iowa, Iowa City, 1873; a Fellow of the American Medical Association, and one of the oldest practitioners of Davenport, Iowa.; for many years secretary and once president of the Scott County Medical Society; trustee and president of the Davenport Academy of Sciences, and for nine years a member of the board of education; died at his home in Davenport, May 21, from cerebral hemorrhage, aged 69.

Arthur Wharton Swann, M.D. College of Physicians and Surgeons in the City of New York, 1907; an instructor in his Alma Mater; assistant attending physician to the Presbyterian Hospital, and chief of the medical clinic of the Presbyterian Dispensary; died in the Manhattan Eye, Ear and Throat Hospital, New York City, May 28, from septicemia, following an operation on the throat a week before, aged 33.

Joseph Franklin Hobson, M.D. Western Reserve University, Cleveland, Ohio, 1886; a Fellow of the American Medical Association; professor of anatomy in his Alma Mater from 1887 to 1892; and professor of clinical surgery in the Cleveland College of Physicians and Surgeons from 1892 to 1906; one of the founders, chief of staff and visiting surgeon to Cleveland General Hospital, and visiting surgeon to St. John's and the City Hospital; local surgeon of the Pennsylvania and Lake Shore and Michigan Southern railroads; and consulting surgeon to the Brotherhood of Railroad Trainmen; died at his home in Cleveland, May 24, aged 52.

George Washington Hosmer, M.D. College of Physicians and Surgeons in the City of New York, 1864; a member of the Medical Society of the State of New York and New York Academy of Medicine; a veteran of the Civil War; and for many years confidential secretary to the late Joseph Pulitzer, editor of the New York *World;* author of numerous articles and books on political economy; died at his home in Summit, N. J., June 3, from senile debility, aged 83.

Henry St. George Lyons Hopkins, M.D. University of Pennsylvania, Philadelphia, 1855; for several years after his graduation a surgeon on transatlantic steamships; surgeon in the confederate service throughout the Civil War, and lieutenant-colonel of the staff of General Pendleton at its close; a resident of Fresno, Cal., for thirty-three years; at one time health officer of Fresno County; died at his home in that city, May 25, aged 78.

Bret Nottingham, M.D. New York Homeopathic College and Hospital, New York City, 1901; a Fellow of the American Medical Association, and a member of the Michigan State Board of Registration and Medicine; city physician and health officer of Lansing, Mich., and local surgeon for the Lake Shore and Michigan Southern System; died in the Harper Hospital, Detroit, May 26, from malignant disease, aged 37.

Daniel C. Gentsch, M.D. Georgetown University, Washington, D. C., 1889; for several years deputy judge and clerk of the probate court of Tuscarawas County, Ohio, and principal examiner of the United States Pension Bureau; died at his home in New Philadelphia, Ohio, May 30, from cerebral hemorrhage, aged 69.

Edwin Y. Chilton, M.D. Miami Medical College, Cincinnati, 1874; a Fellow of the American Medical Association; formerly state senator and president of the Board of Medical Examiners of Minnesota; one of the most prominent practitioners of that state; died at his home in Howard Lake, Minn., May 25, aged 64.

Abijah Johnson, M.D. Denver, Colo., College of Medicine, 1882; a practitioner since 1863; for five years mayor of Earlham, Iowa; for twenty years president of the school board of Montrose, Colo., and once president of the Montrose County Medical Society; died at his home in Glendale, Cal., May 24, aged 76.

Ellis Sanders Potter, M.D. Long Island College Hospital, Brooklyn, N. Y., 1878; one of the oldest colored practitioners of Louisville, and once professor of theory and practice of medicine and pediatrics in Louisville National Medical College; died at his home in Louisville, May 28, from typhoid fever, aged 64.

Mary L. Widdop, M.D. Medical College of Indiana, Indianapolis, 1901; a member of the Indiana State Medical Association; a member of the medical staff of the Northern Hospital for the Insane of the State of Indiana, Longcliff, Logansport; died in that institution May 26, from nephritis, aged 45.

Joseph O. Walkup, M.D. Chicago College of Medicine and Surgery, 1908; Captain, M. C., U. S. Army; once instructor in physiology and assistant in clinical neurology in his Alma Mater; was struck by lightning and instantly killed, June 1, at Fort Bayard, N. Mex.; aged 29.

Christian Charles Hadley Carlson, M.D. Cooper Medical College, San Francisco, 1894; who founded the Mount Shasta Hospital, Yreka, Cal.; died in San Francisco, May 16, from septicemia following an operation for appendicitis, aged 47.

John Nelson Rankin, M D. Vanderbilt University, Nashville, Tenn., 1888; a member of the Indiana State Medical Association; formerly of Winchester, Ky.; died at his home in Cartersburg, Ind., May 18, from heart disease.

William J. Worsham, M.D. Washington University School of Medicine, 1868; a confederate veteran; and the oldest pharmacist of Knoxville, Tenn.; died at his home in that city, May 21, aged 74.

Jacob Carpenter Shimer, M.D. University of Pennsylvania, Philadelphia, 1861; surgeon in the federal service during the Civil War; for thirty-five years a practitioner of Baltimore; died at the Home for Widows and Orphans of Physicians, in that city, May 21, aged 75.

Daniel W. Braden, M.D. Medical College of the State of South Carolina, Charleston, 1852; aged 88; a trustee and treasurer of Washington, Pa., College, for several years; died at his home in Lebanon, Tenn., May 19, from the effects of a carbuncle on the neck.

Glenmore Combs, M. D. Louisville, Ky., Medical College, 1875; a member of the Kentucky State Medical Association; of Winchester; for nearly forty years a practitioner of Clark County, Ky.; died in a church in Winchester, May 17, from heart disease, aged 64.

Daniel Webster Border, M.D. Bellevue Hospital Medical College, 1876; formerly a practitioner of Kearneyville, W. Va.; and at one time a member of the State Board of Agriculture; died at his home in Charlestown, W. Va., May 17, aged 60.

Zachariah B. J. Griffing, M.D. Jefferson Medical College, 1844; a practitioner until the age of 75, and then placed in charge of the poorhouse of Warren, Miss.; died at his home in McGehee, Ark., March 21, from cerebral hemorrhage, aged 92.

Bertram U. Doolittle, M.D. Fort Wayne, Ind., College of Medicine, 1905; of Whiting, Ind.; a Fellow of the American Medical Association, and a specialist on diseases of children; died at his home in Whiting, Ind., about May 16, aged 33.

Emma Mary Eastman Sanborn, M.D. Boston University School of Medicine, 1876; for many years a practitioner of Andover, Mass.; a specialist in the care of imbecile children; died at the Barr Sanitarium, Andover, recently, aged 73.

James Savage Woodward, M.D. George Washington University, Washington, D. C., 1880; a member of the Medical and Chirurgical Faculty of Maryland; formerly a surgeon died at his home in Roland Park, Md., May 28, aged 59.

James Henry M. Karsner, M.D. Jefferson Medical College, 1868; a veteran of the Civil War; and a member of the Medical Society of the State of California; died at his home in Oroville, Cal., May 15, from heart disease, aged 69.

John W. Pipkin, M.D. University of Arkansas, Little Rock, 1890; of Tillar, Ark.; aged 44; a Fellow of the American Medical Association; was shot and killed by his father-in-law, Dr. J. T. Cheairs, at Tillar, Ark., May 30.

Bela W. Coggeshall, M.D. Jefferson Medical College, 1866; a member of the Michigan State Medical Society; of Flint, Mich.; aged 72; was struck by a street-car in Detroit, and died as a result of his injuries, about May 23.

Robert Jones Dysart, M.D. College of Physicians and Surgeons, Chicago, 1900; assistant physician at the State Hospital for the Insane, Winnebago, Wis.; died in that institution, May 25, from heart disease, aged 41.

William B. Swisher, M.D. Rush Medical College, 1854; formerly of Lincoln, Neb.; surgeon of Kentucky Volunteers during the Civil War; died at his home in Los Angeles, May 29, from senile debility aged 88.

Michael P. Stoltz, M.D. Louisville, Ky., Medical College, 1896; a member of the Kentucky State Medical Association; of Louisville; died at the home of his sister in that city, May 18, from heart disease, aged 58.

Thomas Edward McDonald, M.D. Detroit College of Medicine, 1894; a Fellow of the American Medical Association; local surgeon at Holly, Mich., for the Grand Trunk System; died at his home, May 22, aged 46.

Hettie M. Stewart McFall, M.D. Southwestern Homeopathic Medical College, Louisville, 1905; of Fort Wayne, Ind.; died at the home of her daughter in New Albany, Ind., May 21, from nephritis, aged 54.

Donald Duncan McDonald, M.D. McGill University, Montreal, 1887; for many years a practitioner of Petitcodiac, Ont.; physician to the Maritime Penitentiary, Dorchester, Ont.; died January 23, aged 55.

William T. Whitaker, M.D. Fort Worth, Texas, University, 1910; formerly of Fort Worth, Texas; died in his room in McKinney, Texas, May 27, from the effects of an accidental overdose of morphin, aged 32.

William Bayard Carroll, M.D. University of Michigan, Ann Arbor, 1880; died at his home in Chicago, May 30, aged 56.

John Underwood Raymond, M.D. University of Michigan, Ann Arbor, 1875; of Washington, D. C.; medical examiner for the United States Pension Bureau; died at his home in Washington, May 15, aged 63.

George Dresser, M.D. Harvard Medical School, 1862; a member of the Massachusetts Medical Society, and a practitioner of Chicopee, Mass., for more than forty years; died at his home, May 16, aged 76.

John Frank Alcorn, M.D. Western Pennsylvania Medical College, Pittsburgh, 1900; a member of the Medical Society of the State of Pennsylvania; died at his home in Wilkinsburg, Pa., May 25, aged 43.

John Laurence Gartland, M.D. New York University, New York City, 1891; a member of the Ohio State Medical Association; and a resident of Cleveland; died in Lakeside Hospital, May 14, aged 47.

Adolph G. Gehr, M.D. Chicago College of Medicine and Surgery, 1908; formerly an intern in Cook County Hospital, Chicago; died in Los Angeles, Cal., May 26, from valvular heart disease, aged 32.

James M. Cooper, M.D. Jefferson Medical College, 1874; of Reinhold's Station, Pa.; for several years physician of Schuylkill County; died at the home of his son in Shillington, Pa., May 27, aged 64.

Thomas F. Holaday, M.D. Cincinnati College of Medicine and Surgery, 1864; for fifty years a practitioner of Monrovia and Mooresville, Ind.; died at his home in Monrovia about May 19, aged 79.

Alexander B. Ferrell, M.D. Tulane University, New Orleans, 1873; of Wideners, Ark.; a member of the Board of Health of St. Francis County, Ark.; died at Carlisle, Ark., May 19, aged 64.

Leander Anie Steele (license, six years of practice, Michigan, 1900). Formerly a member of the state tax commission; died at his home in Lansing, Mich., March 11, from pneumonia, aged 64.

John Byron Thomas, M.D. Indiana University School of Medicine, Indianapolis, 1909; house physician at Bethel Hospital, Colorado Springs, Colo; died at Wabash, Ind., May 20, aged 26.

Daniel B. Stewart (license, years' of practice, Ohio, 1896). For sixty-three years a practitioner of Williams County, Ohio; died at his home in Jefferson Township, May 25, aged 92.

Lewis Eugene Stanton, M.D. King Eclectic Medical College, Des Moines, Iowa, 1886; a pioneer resident of the Platte Valley; died at his home in Sterling, Colo., May 8, aged 54.

Lewis Hodges Clapp, M.D. New York Homeopathic Medical College, New York City, 1904; of Brooklyn; died at Lakewood, N. J., May 17, after an operation for appendicitis, aged 33.

Marietta E. Livingston Hughes, M.D. Hahnemann Medical College, Chicago, 1876; of Spokane, Wash.; died in Sacred Heart Hospital, Spokane, May 17, from lobar pneumonia, aged 71.

John M. Dunn, M.D. Missouri Medical College, St. Louis, 1861; surgeon in the confederate service throughout the Civil War; died at his home in Richmond, Ark., May 19, aged 80.

Gibson Francis Brock, M.D. Tulane University, New Orleans, 1909; a member of the State Medical Association of Texas; died at his home in Corrigan, Texas, May 26, aged 30.

Henry Cleves Symmes, M.D. University of Pennsylvania, Philadelphia, 1880; a member of the Medical Society of New Jersey; died at his home in Cranbury, N. J., May 8, aged 58.

Amos W. Bickford, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1865; a pioneer practitioner of Pasadena, Cal., died at his home in that city, May 21, aged 76.

Thomas Egbert Enloe, M.D. University of Nashville, Tenn., 1874; of Nashville; died at the home of his daughter in that city, from cerebral hemorrhage, May 26, aged 69.

John J. Bradley, M.D. Minnesota Hospital Medical College, Minneapolis, 1885; died at his home in Milwaukee, May 12, aged 82.

Littleton B. Richards, M.D. Memphis Hospital Medical College, 1898; died at his home in Avery, Ark., May 14, aged 42.

John H. Page, M.D. University of Louisville, Ky., 1875; died at his home in Madill, Okla., May 16, aged 62.

The Propaganda for Reform

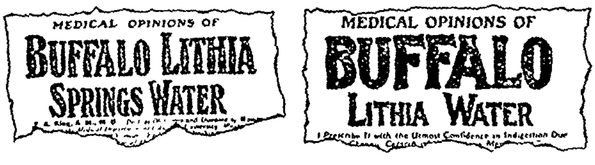
In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

BUFFALO LITHIA WATER

Contains One-Fifth as Much Lithium as Potomac River Water

Some years ago, Alexander Haig evolved the theory that most diseases are due to uric acid. The data on which he founded his theory were not corroborated by scientific men, and investigation showed that his methods were unreliable. In spite of the fact that Haig's theories are utterly discredited, and have been for years, the uric acid fallacy still persists, although it is now largely confined to the public. Shrewd business men, especially those who are more intent on making money than they are concerned with the manner in which that money is made, owe much to Haig's theory. As a business proposition, uric acid has been one of the best-paying fallacies on the market—and possibly still is. It is only necessary to refer to The Journal's recent article[1] on the Turnock mail-order medical fraud to emphasize this fact.

Contemporary with, and to a certain extent a corollary of, the uric acid fallacy was another, *viz.*, that lithium would eliminate uric acid. This at once gave a good working principle for the proprietary men. Uric acid, we were told, causes disease; lithium, we were also told, would eliminate uric acid; therefore, lithium is the new elixir of life! Could anything be simpler?



MEDICAL OPINIONS OF
BUFFALO LITHIA
SPRINGS WATER

MEDICAL OPINIONS OF
BUFFALO
LITHIA WATER

NOW AND THEN

Showing how "Buffalo Lithia Water" in the course of time became "Buffalo Lithia *Springs* Water." The government has shown that, to obtain a therapeutic dose of lithium from Buffalo Lithia Springs Water, *it would be necessary to drink 200,000 gallons of the water.* The government also declared that Potomac River water contained five times as much lithium as does Buffalo Lithia Springs Water.

Accepting this theory, it was inevitable that mineral waters containing lithium salts should become highly popular. Many exploiters of mineral waters began to place most emphasis on the lithium salts in their waters even in those cases in which lithium was present in such infinitesimal amounts as to render its detection impossible by any but spectroscopic methods.

One of the best known, because most widely advertised, of the so-called lithia waters is Buffalo Lithia Water—or what used to be called Buffalo Lithia Water. After the Federal Food and Drugs Act came into effect, by which falsification on the label was penalized, the name of Buffalo Lithia Water was changed to Buffalo Lithia Springs Water. The reason for this change was that when Buffalo Lithia Water was subjected to examination by the government chemists it was found to contain so little lithium that the amount present was unweighable—it could be demonstrated only by the spectroscope. It was evidently, therefore, not a lithia water *in that it did not contain—at least in quantities* that could be consumed—an amount of lithium that would give the therapeutic effects of lithium: Possibly the company imagined that by changing the name from "Buffalo Lithia Water" to "Buffalo Lithia Springs Water" it had cleverly evaded the federal law. *Their argument was to this effect:*

---

1. The Journal A. M. A., May 23, 1914, p. 1675.

The springs from which this water is taken are known as Buffalo Lithia Springs; therefore, it is not a misstatement of facts to call this Buffalo Lithia Springs Water.

WHAT IS A LITHIA WATER?

The Supreme Court of the District of Columbia, holding a district court, has recently given an opinion on the Buffalo Lithia Springs Water case. The findings of the court are refreshingly simple, and characterized by that broad commonsense view that is becoming increasingly more common among modern jurists. Read Judge Gould's opinion as to what constitutes a lithia water:

> "Speaking generally, and as an individual of average intelligence and information, it would seem that if one were offered a water which the vendor told him was a 'lithia' water, one would have the right to expect enough lithium in the water to justify its characterization as such, thus differentiating it from ordinary potable water; and this amount would reasonably be expected to have some effect on the consumer of the water by reason of the presence of the lithium."

Certainly a reasonable attitude, and one which the man in the street not only can understand but will agree with. Then came the question as to the actual lithium content of Buffalo Lithia Springs Water, and the court said:

> "For a person to obtain a therapeutic dose of lithium by drinking Buffalo Lithia Water he would have to drink from one hundred and fifty thousand to two hundred and twenty-five thousand gallons of water per day. It was further testified, without contradiction, that Potomac River water contains five times as much lithium per gallon as the water in controversy."

SOME TESTIMONIALS

Here, then, is a water that has for years been advertised first, in medical journals, and later, in lay publications, as a "lithia water" yet, actually, it contains less lithium, five to one, than is to be found in ordinary river water. This is a point for physicians to ponder well over. Turn to the back volumes of medical journals and read, both in the advertising and reading pages, the elaborate testimonials, given by men high in the medical profession, on the marvelous effects obtained by the use of Buffalo Lithia Water. Read the following in light of the fact that the water from the Potomac River contains five times as much lithium as Buffalo Lithia Water:

> "In the class of cases in which lithia, soda and potash are regarded as most specially indicated, I have obtained far better results from the Buffalo Lithia Waters than from any of the preparations of the lithium salts of the Pharmacopeia." *(Statement by a member of the Faculty of Medicine of Paris, France,* etc.)

> "Its [Buffalo Lithia Water] therapeutic effects, in my practice, have been vastly superior to those obtained from Lithia Tablets or other Lithia preparations." *(Statement by an ex-president of the University College of Medicine, Richmond, Va., etc.)*

> "It [Buffalo Lithia Water] is strikingly superior to emergency solutions of lithia tablets and pure water, even where the said solution is an exceedingly strong one." *(Statement by a former Professor of Clinical Medicine of the College of Physicians and Surgeons, New York, and vice-president of the American Medical Association, etc.)*

> "When Lithia is indicated, I prescribe Buffalo Lithia Water in preference to the Salts of Lithia, because it is therapeutically superior to laboratory preparations of Lithia." *(Statement by a former professor in the Medical College of Virginia and ex-president of the Medical Society of Virginia, etc.)*

> "Buffalo Lithia Water . . . by its richness of composition of Lithia, is of marvelous efficacy, in cases of gout, of chronic, articular, and muscular rheumatism . . ." etc. *(Statement by former Physician in Ordinary to the Pope; Member of Academy of Rome, etc.)*

> "I have tried carbonate of lithia dissolved in water in various proportions; but it certainly does not have the same effect as Buffalo Lithia Water." *(Statement by a former Surgeon-General of the U. S. Army, etc.)*

These are but a few of many testimonials from physicians that might be quoted. They are interesting from many points of view. They show the worthlessness of testimony of this sort—no matter from what source—and the fallacy of that based on so-called clinical evidence.

To go back to the court's findings: In the case of the government against Buffalo Lithia Springs Water, one other judicial opinion is worthy of attention, that referring to the attempt on the part of the exploiters of the water to circumvent, on a technicality, the evident intent of the Food and Drugs Act. Said Judge Gould:

> "The argument seems to be that if Buffalo Lithia Springs are falsely named, being called 'Lithia' Springs, when they do not flow water containing lithium, therefore the proprietors have the right to sell the product as being Buffalo Lithia Springs Water, thus perpetuating on the public the misnomer connected with the origin of the water. It is not apparent how the deceit practiced on the public by the label is mitigated by carrying it back to the designation of the spring from which the water comes."

For years no one, apparently, ever criticised the claims made for this product. Finally, we got the Food and Drugs Act and the federal officials, acting under the authority vested in them by that law, in December, 1910, declared Buffalo Lithia Water misbranded. Thus this old established vested interest was attacked. The company, of course, fought. It first demurred to the charge brought, and in April, 1912, the demurrer was sustained. At the same time an amended libel was filed by the government, which the company again demurred to. This demurrer was overruled in June, 1912, whereon the company in December, 1912, filed an answer denying that the water was misbranded. The question has now (1914) been finally decided by the court sitting as a jury, the matter having been submitted by agreement to the court.

Buffalo Lithia Water has been sold since 1878. During this period undoubtedly many physicians have prescribed enormous quantities of this water, and many more laymen have taken the water on their own initiative, based on the advertised claims made for it. Practically all who purchased the water, whether directly or on the advice of physicians, did so in the belief that they were getting lithium. Had they known that, to get a therapeutic dose of lithium they would have had to drink 200,000 gallons of Buffalo Lithia Water, they would have felt, and rightly so, that they were the victims of an expensive hoax.

THE GERMAN PROPAGANDA FOR REFORM

Appreciation by a German Lay Publication

Of all those interested in the reform of the proprietary drug business, the patient has the most at stake—and the public is beginning to understand this fact. If physicians are slow in recognizing the necessity for improvement, laymen will eventually demand reform in their own interests. The movement, therefore, will not be halted by the indifference of the unprogressive element of the medical profession. New evidence of this fact is furnished by a recent editorial comment by the German lay periodical, *Wohlfahrt und Wirtschaft* (Public Welfare and Economics), on the Arzneimittel-Kommission, a German organization resembling in purpose if not in scope the Council on Pharmacy and Chemistry of the American Medical Association.

"One would suppose," says this lay journal, "that medicinal preparations which did not win the approval of scientific medicine would not be used by any physician, but the contrary is the case. In fact, those new medicinal preparations or old ones with new names that flood the market far surpass the actual demand according to the judgment of all authorities. The impartial advisers in this field, practitioners and members of medical faculties, demand, as a matter of public welfare that this overproduction should be regulated in the interests of the sick, the consumers; but, unfortunately, a medical man, like any one else, is impressed by the suggestion from advertising done on a large scale."

The movement for reform, *Wohlfahrt und Wirtschaft* goes on to explain, is not exclusively a medical one. It is a part of the reaction of "economic common sense" against a too individualistic commercial system which leads to overproduction. In other words, it is a reaction against the system of making things because they can be sold rather than because they are needed. The interests of producers need to be harmonized with those of consumers, not merely in the drug trade alone, but throughout the commercial world. *Wohlfahrt und Wirtschaft* quotes with unqualified approval the Arzneimittel-Kommission's statement of its position: An industry which serves the science of healing must be guided by that science. (*Eine Industrie die der Heilweissenschaft dient, hat sich nach der Heilweissenschaft zu richten.*)

The movement for reform in Germany has apparently gathered sufficient impetus among the laity to go on of its own momentum, even though, with one exception, German medical journals, reluctant to lose the advertising of drug houses by publishing criticisms of their wares, have become lukewarm, if not antagonistic, to the efforts of the Arzneimittel-Kommission. The one exception is the *Therapeutische Monatshefte*, which, in its May issue, quotes in full the editorial just referred to and makes the following comment: "These lines reveal such intimate knowledge and correct judgment of existing conditions that the suggestions advanced in regard to possible reforms deserve serious consideration. For us physicians the editorial is important in that it recognizes that the efforts of the profession to accomplish the reforms aimed at are rational and beneficial from the standpoint of general economics and the public welfare."

Association News

PUBLIC HEALTH SUNDAY IN PHILADELPHIA

Following the custom observed for several years past, the Council on Health and Public Instruction of the American Medical Association has offered this year to furnish speakers for all Philadelphia churches desiring an address on public health on Sunday, June 21, the Sunday preceding the Atlantic City *session. A list of the churches, speakers and subjects* follows:

Belmont Avenue Baptist, Corner of Belmont and Westminster, Rev. W. A. Spinney, Pastor.
Morning, 10:30: Dr. J. W. Kerr, Assistant Surgeon-General, U. S. P. H. S., Washington, D. C., "Opportunities of the Church in Public Health Endeavor."

Chelten Avenue Baptist, Chelten Avenue above Boyer Street, Rev. P. R. Hayward, Pastor.
Evening, 7:45: Dr. Calvin S. White, Portland, Ore., "Socialization of Medicine."

Chestnut Street Baptist, Fortieth and Chestnut streets, Rev. George D. Adams, Pastor.
Evening, 8: Dr. Thomas D. Coleman, Augusta, Ga., "Public Health."

Dotterel Memorial Baptist, Twenty-Fourth and Dickinson streets, Rev. E. D. Shull, Pastor.
Evening, 8: Dr. Claude A. Smith, Atlanta, Ga., "Public Health."

Fifth Baptist, Eighteenth and Spring streets, Rev. W. Q. Rosselle, Pastor.
Morning, 10:30: Dr. W. W. Grant, Denver, "Public Health."

First Baptist Germantown, Price Street near Germantown Avenue, Rev. Thomas S. Samson, Pastor.
Morning, 10:30: Dr. Oscar Dowling, New Orleans, "Public Health."

Fiftieth Baptist, North Seventh Street and Susquehanna Avenue, Rev. J. Francis Behrens, Pastor.
Morning, 10:30: Dr. Frank B. Wynn, Indianapolis, "Mental Hygiene in Relation to Disease."

The Baptist Temple, Broad and Berks street, Rev. Russell H. Conwell, Pastor.
Morning, 10:30: Dr. Guilford H. Sumner, Des Moines, Iowa, "Disease and Its Prevention."

Immanuel Baptist, Twenty-Third and Summer streets, Rev. William Oswald, Pastor.
Morning, 10:30: Dr. Charles S. Williamson, Chicago, "The Relationship of Mortality and Public Health."

Northwest Baptist, Lehigh Avenue and Twenty-Eighth Street, Rev. W. Dallas Cope, Pastor.
Evening, 7:45: Dr. Robert M. Funkhouser, St. Louis, "Eugenics."

Second Baptist Germantown, Germantown Avenue and Upsal Street, Germantown, Rev. Charles H. Dodd, Pastor.
Morning, 10:30: Dr. H. A. Kelly, Baltimore, "Public Health."

Temple Baptist, Twenty-Second and Tioga streets, Rev. Thomas C. Bird, Pastor.
Morning, 10:30: Dr. Edward Jackson, Denver, "The Gospel of Health."

Third Baptist, Broad and Ritner streets, Rev. G. W. Drew, Pastor.
Morning, 10:30: Dr. Hugh Cabot, Boston, "The Control of Disease by Public Opinion."

Tioga Baptist, Broad below Tioga Street, Rev. Rutger Dox, Pastor.
Morning, 10:30: Dr. Jere L. Crook, Jackson, Tenn., "The Stewardship of the Body."

Wayne Avenue Baptist, Wayne Avenue and Queen Lane, Germantown, Rev. B. L. Newkirk, Pastor.
Evening, 8: Dr. Charles P. Emerson, Indianapolis, "The Message of Modern Medicine."

Woodland Avenue Baptist, Woodland Avenue east of Sixty-Fourth Street, Rev. Rittenhouse Neisser, Pastor.
Evening, 7: Dr. Richard C. Newton, Montclair, N. J., "The Human Body."

First Christian, Berks and Marvine streets, Rev. Irving S. Chenoweth, Pastor.
Morning, 10:30: Dr. Morgan Smith, Little Rock, Ark., "Public Health, the Paramount Issue."

Prichard Memorial Lutheran, Sixty-Third and Elmwood Avenue, Rev. J. William H. Heinty, Pastor.
Evening, 7:45: Dr. James P. Warbasse, Brooklyn, "The Socialization of Public Health."

Fletcher Methodist Episcopal, Fifty-Fourth and Master streets, Rev. R. H. Crawford, Pastor.
Evening, 7:45: Dr. Miles F. Porter, Fort Wayne, Ind., "A New Health Gospel."

Kynett Memorial Methodist Episcopal, Seventeenth and Cayuga streets, Rev. Harry P. Boughey, Pastor: Dr. G. V. I. Brown, Chicago, "The Health of Children and Its Influence in Moral, Physical and National Development."

Norris Square Methodist Episcopal, Susquehanna Avenue and Mascher Street, Rev. E. F. Hoffman, Pastor.
Evening, 7:45: Dr. Henry D. Holton, Brattleboro, Vt., "Social Conditions as They Affect Daily Life."

Olivet Methodist Episcopal, Sixty-Third and Grays Avenue, Rev. S. K McConnell, Pastor.
Evening, 7:45: Dr. J. C. M. Floyd, Steubenville, Ohio, "Social Waste."

Port Richmond Methodist Episcopal, Indiana Avenue and Thompson Street, Rev. G. B. Burnwood, Pastor.
Evening, 7:45: Dr. Thomas N. Gray, Newark, N. J., "Save the Babies."

Providence Methodist Episcopal, Front Street and Allegheny Avenue, Rev. Walter B. Smith, Pastor.
Evening, 7:45: Dr. C. E. Cantrell, Greenville, Tex., "Public Health."

Siloam Methodist Episcopal, East Susquehanna above Thompson, Rev. John C. Petre, Pastor.
Morning, 10:30: Dr. Lucien Howe, Buffalo, N. Y., "The Morality of Eugenics."

Summerfield Methodist Episcopal, corner Tulip Avenue and East Dauphin, Rev. F. A. Gacks, Pastor.
Evening, 7:45: Dr. Thomas S. Cullen, Baltimore, "Cancer."

Twenty-Ninth Street Methodist Episcopal, Corner Twenty-Ninth and York streets, Rev. John D. C. Hanna, Pastor.
Morning, 10:30: Dr. V. C. Vaughan, Ann Arbor, Mich., "The Evolution of the Superman."

Covenant Presbyterian Germantown, Chelten Avenue and Limekiln Pike, Rev. Harle W. Hathaway, Pastor.
Morning, 10: Dr. S. L. Jepson, Wheeling, W. Va., "The Fallacy of Faith Healing."

Emmanuel Presbyterian, Girard Avenue and Forty-Second Street, Rev. Edward S. Bowman, Pastor.
Evening, 7:45: Dr. Woods Hutchinson, New York, "Am I My Brother's Keeper?"

Ninth Presbyterian, Fifty-Seventh Street and Washington Avenue, Rev. John A. Higgons, Pastor.
Evening, 8: Dr. R. E. Brenneman, Pittsburgh, "Prevention of Cancer."

Puritan Presbyterian, Second and Clearfield streets, Rev. James G. Raymond, Pastor.
Evening, 7:45: Dr. E. A. Hines, Seneca, S. C., "Vital Problems in Preventive Medicine."

West Hope Presbyterian, Preston and Aspen streets, Rev. Charles E. Bronson, Pastor.
Evening, 7:45: Dr. H. W. Wiley, Washington, D. C., "Public Health."

West Park Presbyterian, Fifty-Fourth Street and Lansdowne Avenue, Rev. C. Grant Hopper, Pastor.
Evening, 7:45: Dr. Thomas D. Crothers, Hartford, Conn., "Scientific Side of the Temperance Question."

Overbrook Presbyterian, Corner City and Lancaster avenue, Rev. Guido Bossard, Pastor.
Evening, 8: Dr. C. S. Bacon, Chicago, "How to Prevent Sickness and Prolong Life."

Fourth United Presbyterian, Nineteenth and Fitzwater streets, Rev. J. C. Scouller, Pastor.
Morning, 10:30: Dr. Angus McLean, Detroit, "Health Education a State Duty."

Dales Memorial United Presbyterian, Thirty-Second, corner Cumberland, Rev. T. B. Turnbull, Pastor.
Morning, 11: Dr. John L. Heffron, Syracuse, N. Y., "Public Health and Public Morals."

All Saints Episcopal, Torresdale, Rev. A. R. Van Meter, Rector.
Morning, 10:30: Dr. W. C. Rucker, Assistant Surgeon-General, U. S. P. H. S., Washington, D. C., "The Church and Industrial Disease."

St. John's Episcopal, Brown Street near Third, Rev. George Chalmers Richmond, Rector.
Evening, 7:45: Dr. Joseph C. Bloodgood, Baltimore, "Control of Cancer."

Calvary Reformed, Twenty-Ninth and Lehigh Avenue, Rev. F. H. Fisher, Pastor.
Evening, 7:30: Dr. S. A. Knopf, New York, "How to Improve the Physical, Mental and Moral Condition of our Schoolchildren."

Heidelberg Reformed, Nineteenth and Oxford streets, Rev. Rufus C. Zartman, Pastor.
Evening, 7:45: Dr. A. L. Benedict, Buffalo, "Public Intelligence and Information as Factors of Public Health."

Mt. Hermon Reformed, Sixteenth and Wingohocking streets, Rev. C. B. Alspach, Pastor.
Evening, 8: Dr. B. R. McClellan, Xenia, Ohio, "Conservation of Child Life."

St. Mark's Reformed, Fifth Street above Huntingden Pt., Rev. George A. Sheer, Pastor.
Morning, 10: Dr. Charles H. Cook, Natick, Mass., "Public Health."

Girard Avenue Unitarian, Girard Avenue above Fifteenth Street, Rev. K. E. Evans, Pastor.
Morning, 10:45: Dr. Walter B. Cannon, Boston, "Social Responsibilities Arising from Medical Progress."

Bethel United Evangelical, Twelfth Street above Lehigh Avenue, Rev. John W. Slack, Pastor.
Evening, 7:45: Dr. L. Mervin Maus, Colonel Medical Corps, U. S. Army, Governor's Island, N. Y., "The Effect of Alcohol on Society."

All Souls Universalist, Forty-Seventh Street and Larchwood Avenue, Rev. Thomas W. Illman, Pastor.
Dr. G. M. Illman, Philadelphia, "Some Things the Public Should Know about Medicine and The American Medical Association."

In addition, through the courtesy of Archbishop Prendergast, the 104 Catholic priests of Philadelphia have been supplied with copies of a special address on "Our Progress in Medicine," by Dr. J. J. Walsh of New York. This address will be used by the parish priests as the basis for sermons on public health which will be delivered to the congregations on Sunday morning, June 21.

Correspondence

The Necessity of Adopting State Laws Regulating the Nature of the Liquids to Be Used for Embalming Purposes

To the Editor:—A recent experience brought forcibly to my notice the desirability that laws regulating the nature of embalming fluids should be enacted. In analyzing certain organs from a body in which there were many reasons to suspect arsenical poisoning, I was able to isolate large amounts of mercury and arsenic. Examination of the embalming fluid used in this case showed it to contain arsenic and mercury. On this account no case could be made out against the supposed administrators of the poison.

When one realizes that there are no restrictions in this country regarding the nature of embalming fluids to be used except in the states of New York, New Jersey and Michigan, the chance of detecting poisoners after the embalming is done is rather slim. This is especially true as regards the use of arsenic and mercury, as they are almost invariably present in the embalming fluids now used. In Michigan the law prohibits only the use of arsenic. In New Jersey the law provides that "no person shall employ for the purpose of embalming or preserving any dead human body, any arsenical solution nor any other poisonous agent which may, by its presence in the viscera, prevent the detection of criminal uses of said poisonous agents before the death of the individual occurred."

The state of New York has by far the best law regulating the nature of the embalming fluid to be used. It is as follows:

> No embalmer shall inject into any dead human body for the purpose of preserving, disinfecting or embalming the same any fluid that is not a thorough germicide in the proportions ordinarily used in embalming, that is, eight parts of fluid to 150 parts of body-weight, or that contains arsenic, zinc, mercury, copper, lead, silver, antimony or chloral or any substance or compound that contains either or any of them, or any poisonous alkaloid. Except that nothing in this regulation shall apply to the use of the above-named substances in any duly incorporated medical college or scientific institution by those having in their legal possession human cadavers intended to be used for the purpose of medical study or other legitimate purposes.

The New York regulations also prohibit the sale of embalming liquids containing the poisons above mentioned and provide for the bacteriologic examination, chemical analyses and certification of such liquids by the board.

It is most desirable that the other states in this country enact laws similar to those adopted in New York State. At the next meeting of the Pennsylvania legislature, I shall have introduced a bill similar to that adopted in New York. It may be of interest to observe that France in 1846 prohibited the use of arsenic in embalming fluids.

Jacob Rosenbloom, M.D., Ph.D., Pittsburgh.

[Comment.—Reference to the laws of the various states would indicate that our correspondent is too sweeping in his statement as to the lack of restrictions outside of New York, New Jersey and Michigan.

Illinois has a statute on this specific point, and while in some ways it may not be quite so effective as the New York law, it would seem to carry more weight, inasmuch as a penalty is attached. See Illinois Sess. Laws, 1907, page 257, and Chapter 31, Sec. 25, Illinois Sess. Laws, 1907.

Iowa vested its Board of Health with jurisdiction over embalmers. This board has promulgated a set of rules precluding the use of other material than that which is specified in the rules, from an examination of which it appears that the objectionable substances cannot be used. See Chap. 4. Rule 3, Regulations of the Iowa State Board of Health, on the care of the dead. See also Chap. 16, Title 12, Iowa Code, as to the powers of the State Board of Health.

South Dakota similarly vests its board with a like jurisdiction. This state has also forbidden the use of objectionable poisons. See Regulations of the South Dakota State Board of Health for 1913, Sec. 144.

Moreover, in a number of states in which the use of specific poisons is not forbidden, the ground is nevertheless fairly well covered in the provision that "it shall be unlawful for any person or persons to embalm . . . any dead body . . . in case the death is believed to be due to other than natural causes, or the cause thereof is unknown . . . without a proper death certificate which has been signed or approved by the coroner." See 31 and 32 of the statutes at large, U. S., Sections 683, 684. Also Kansas Embalmers Law for 1912, Sec. 9764; Chap. 181, Maine Sess. Laws, 1911, Section 12; Rules and Regulations of the Massachusetts Board of Embalmers for 1908, Sec. 9; Chap. 76, New Hampshire Sess. Laws, 1899, Sec. 5; Rules and Regulations of Rhode Island Board of Embalmers for 1912, Sec. 8; and Act 216, Vermont Sess. Laws, 1910, Sec. 7.

Finally, a number of states vest their boards of health with power to make regulations touching the proper care of the dead. See Conn. Code as amended, 1909, Sec. 1962; and rules of the Connecticut Board of Health, Feb. 5, 1902; Laws and Regulations touching on embalmers, Idaho, 1909, Sec. 6; Chap. 101, Minnesota Sess. Laws, 1905; Embalmers Law, Oregon, Sec. 9; and Chap. 420, Wis. Sess. Laws, 1905, Sec. 8; Cf. Wisconsin Code, Sec. 1408-1409.—Ed.]

McClure's Mistake

To the Editor:—The Journal is to be congratulated on the promptness with which it has commented on the article "Painless Child-Birth" in the June issue of *McClure's*.

As the article has much in common with the paper Krönig read before the Chicago Gynecological Society in November, 1913, entitled, "The Difference between the Older and the Newer Treatments by X-Ray and Radium in Gynecological Diseases," and published in the May issue of *Surgery, Gynecology and Obstetrics,* I was impressed that the data for the article in *McClure's* could not have been obtained without at least the passive cooperation of Krönig, Gauss, or both. I, therefore, wrote *McClure's* to inquire if the article had been gone over by Krönig and Gauss and published with their consent. Enclosed you will find a copy of the reply received from *McClure's*, which answers the editorial comment in The Journal, June 6, 1914, page 1815, which states that "If the publication was sanctioned by either or both of them it indicates an advertising initiative which bids fair to rival Friedmann," and will at least, if published, enlighten the members of the profession in this matter.

I read the article in *McClure's* with much interest, but was amazed that it had slipped through the editorial department, as it reads like an advertisement put out by a charlatan, or by a pharmaceutical house with its "ethical proprietary" advertised to the public.

S. E. Tracy, M.D., Philadelphia.

COPY OF LETTER RECEIVED FROM MC CLURE'S

McClure's Magazine
The McClure Publications
Fourth Avenue and 20th Street, New York.

Editorial Department.

May twenty-fifth, 1914.

Dear Doctor:

In reply to your letter of May nineteenth, I have to say that the article on "Painless Childbirth" in June McClure's, is technically correct and was read by Prof. Krönig and Dr. Gauss and published with their consent.

Yours very truly,

(Signed) J. Willard Connely

Dr. Stephen E. Tracy,
1527 Spruce Street.
Philadelphia, Pa.

Stubbornness.—Obstinacy is the result of the will forcing itself into the place of the intellect.—Schopenhauer.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE ABSORPTION OF IRON FROM MINERAL WATERS

To the Editor:—In a Current Comment on this subject (The Journal, March 14, 1914, p. 856), there is a statement to the effect that both organic and inorganic iron can be absorbed and satisfactorily carry out the purposes for which they are ordinarily administered. Will you please give me references to the results which you have considered evidence as to the truth of that statement? I wish to present the proofs to a class in dietetics at the University.

Maria Madden, Lawrence, Kan.

Answer.—The evidence regarding iron absorption was mostly interpreted prior to the first clear demonstration that the bowel forms the most important channel for the excretion of this element. The failure to find any increase in the amount of iron eliminated with the urine by the kidneys after the ingestion of the element in some form or other was taken as an indication that it had not been absorbed. To-day we know that it can be both absorbed and excreted by the intestinal wall. For this reason references to the very early literature on the subject now have merely historical interest.

The conclusion that both forms of iron compounds, namely, the organic and the inorganic or ionized types, can be absorbed, is based on a variety of experimental evidences. The total intake and output of iron have been ascertained in some cases, and the favorable balance or retention of iron accepted as evidence. The intestinal mucosa has been examined by microchemical methods to demonstrate the entrance of ingested iron. Iron has been detected in the thoracic lymph soon after the introduction of ferric chlorid into the stomach. Various organs and even the entire bodies of animals have been examined to learn whether they have become enriched by the forms of iron compounds administered. Animals have been rendered anemic by hemorrhage and thereon the efficiency of the two kinds of iron derivatives in restoring the hemoglobin of the blood ascertained. Clinical observations on anemic patients have been drawn on to contribute to the same end.

The debate on the subject has been prolonged. The absorption of inorganic iron is now universally admitted. The question whether it can serve *directly* for hemoglobin formation has not been so easily answered. Some have inclined to the view that the absorbed inorganic iron acts merely as a stimulus to the hemopoietic organs to convert the organic forms into the blood pigment. The changing views of digestion formulated in recent years make it easier to understand that all iron probably becomes ionized in the intestine before absorption, and that synthetic transformations of the element occur later in any event, if it is to be retained in the organism.

An elaborate review of the subject, with a complete bibliography to 1906, has been prepared by Meyer, E.: Ueber die Resorption und Ausscheidung des Eisens, *Ergebn. d. Physiol.*, 1906, v, 698. An excellent discussion of the question is furnished in Sherman, H. C.: Chemistry of Food and Nutrition, New York, the Macmillan Company, 1911, p. 232, and following. Abderhalden's contributions are considered in his Text-Book of Physiological Chemistry, translated by Hall, New York, John Wiley & Sons.

THE BOAS EXTRA-ANAL TREATMENT OF HEMORRHOIDS

To the Editor:—Please describe the Boas extra-anal treatment of hemorrhoids.

A. M., Detroit.

To the Editor:—What is the Boas method for the extra-anal treatment of hemorrhoids?

A. J. Nossaman, M.D., Pagosa Springs, Colo.

Answer.—The Boas method consists of extruding the tumors, applying Bier's suction to them until a ring of edema forms, the time being about sixty minutes, and leaving the tumors outside the anus. The hemorrhoids shrivel in consequence of the interruption to the circulation and eventually disappear. The patients are confined to bed about two weeks. The following articles may be referred to:

Boas, I.: Extra-Anal, Non-Operative Treatment of Hemorrhoids, *Arch. f. Verdauungskr.*, 1909, xv, No. 2; abstr., The Journal, March 22, 1909, p. 1725.

Boas, I.: Bloodless Cure of Hemorrhoids, *München. med. Wchnschr.*, Jan 30, 1912; abstr., The Journal, March 9, 1912, p. 742.

A PRACTICAL STATE-WIDE CAMPAIGN IN VENEREAL PROPHYLAXIS AND SEX INSTRUCTION, INCLUDING LEGISLATION AGAINST QUACKS

Oregon has had in operation for over two years a plan of education in venereal prophylaxis and sex instruction. The movement originated in Portland in 1911 in a call issued by a committee of the Y. M. C. A. for a meeting of citizens to combat the social evil in that city. An organization was effected which later merged into the Oregon Social Hygiene Society. Its efforts have been extended to the entire state, and the legislature and State Board of Health have cooperated in the work. The head of the society from the beginning has been the state health officer, Dr. Calvin S. White.

During the first year the work was confined almost entirely to Portland. Meetings were held among the young people, the parents, and in various business houses and industrial establishments. Talks on health topics were given, gradually introducing the subject of sex hygiene. State Board of Health notices regarding venereal diseases were given publicity and circulars were distributed through paymasters and other channels. Permanent and temporary traveling exhibits in the form of posters and panels were also provided in Portland and a large number of other cities of Oregon. These concerned the subjects of sex hygiene, venereal prophylaxis, "men's specialists" quacks and their fraudulent methods, and offered free advice by the State Board of Health.

LEGISLATION AFFECTING QUACKS

The state legislature in 1913 passed the following law in regard to quacks and quack advertising:

> Sec. 2095. Any person who shall advertise or publish any advertisement intended to imply or be understood that he will restore manly vigor, treat or cure lost manhood, lost power, stricture, gonorrhea, chronic discharges, gleet, varicocele or syphilis, or any person who shall advertise any medicine, medicinal preparation, remedy or prescription for any of the ailments or diseases enumerated in this act shall be deemed guilty of a misdemeanor and upon conviction thereof shall be punished by a fine of not less than $100 nor more than $1,000, or by imprisonment in the county jail for a period of not less than six months nor more than twelve months, or by both such fine and imprisonment. Any owner or managing officer of any newspaper in whose paper shall be printed or published any such advertisement as is described in this act shall be deemed guilty of a misdemeanor and upon conviction thereof shall be punished by a fine of not less than $100 nor more than $1,000, or by imprisonment in the county jail for a period of not less than six months, or by both such fine and imprisonment.

As a result of the passage of this law and of the steadily growing public sentiment against the methods of quack doctors, their business steadily decreased. The cooperation of the newspapers of Portland (with one exception) was secured so that a minimum of advertising space was available for the quack doctors. Many offices were closed and the business of others decreased. In 1911 grand jury indictments were obtained in Portland against a number of advertising quacks for violation of the state law which prohibits advertising to cure certain specific ailments. The newspapers of the state also generally support the movement, and only two or three continued to publish one or more advertisements of the "men's specialists." As shown by the report of the society, at the end of 1913 there were in the whole state only five of the old quack concerns, and in addition about five Chinese concerns which did a general practice. None of them advertise as "men's specialists"; all purport to treat both men and women for various diseases. The only remaining "museum of anatomy" in the state went out of business during the year. Among the quack institutions named in the poster campaign are the "Oregon Medical Institute," "Pacific Coast Medical Co.," "Dr. A. G. Smith, specialist," "Dr. Lindsay," "Dr. Warren," "Dr. C. K. Holsman," "Truthful Travis Oriental Remedy Co.," "Asiatic Acme Remedy Co.," and "J. J. Keefe, Ph.G., M.D."

In addition to the act regarding fraudulent practice and advertising, the legislature of 1913 lent its substantial support to the Oregon Social Hygiene Society in the form of an appropriation of $10,000, to be paid direct to the society for carrying on and extending its work throughout the state. The campaign is an example of the good results which may be achieved by united efforts encouraged by newspaper and legislative assistance.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 14. Chairman, Dr. W. H. Sanders, Montgomery.

Alaska: Juneau, July 7. Sec., Dr. Henry C. De Vighne, Juneau.

Arizona: Phoenix, July 7-8. Sec., Dr. John Wix Thomas, Phoenix.

California: Los Angeles, June 16. Sec., Dr. C. B. Pinkham, 135 Stockton St., San Francisco.

Colorado: Denver, July 7. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, July 14-15. Sec., Dr. Chas. A. Tuttle, New Haven. Homeopathic: New Haven, July 14. Sec., Dr. Edwin C. M. Hall, New Haven. Eclectic: New Haven, July 14. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

Delaware: Dover and Wilmington, June 16-18. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

Florida: Palatka, June 17-18. Sec., Dr. E. W. Warren, Palatka.

Illinois: Chicago, June 23-25. Sec., Dr. C. St. Clair Drake, Springfield.

Indiana: Indianapolis, July 14-16. Sec., Dr. W. T. Gott, State House, Indianapolis.

Kentucky: Louisville, June 15-17. Sec., Dr. A. T. McCormack, Bowling Green.

Maine: Augusta, July 7-8. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Mar[illegible] lar Board: Sec., Dr. J. McP. Scott, [illegible] nore, June 15. Sec., Dr. O. N. Duvall, [illegible]

Mississippi: Jackson, June 16-17. Sec., Dr. E. H. Galloway, Jackson.

Missouri: St. Louis, June 15-17. Sec., Dr. J. A. B. Adcock, Jefferson City.

Montana: Helena, June 30-July 2. Sec., Dr. Wm. C. Riddell, Helena.

New Hampshire: Concord, July 1-2. Regent, Mr. H. C. Morrison, Concord.

New Jersey: Trenton, June 15-16. Sec., Dr. H. G. Norton, 429 E. State St., Trenton.

New Mexico: Santa Fe, July 13. Sec., Dr. W. E. Kaser, East Las Vegas.

New York: June 23-26. Chief of Examinations Division, Mr. Harlan H. Horner, Department of Education, Albany.

North Dakota: Grand Forks, July 7. Sec., Dr. G. M. Williamson, Grand Forks.

Oklahoma: Oklahoma City, July 14. Sec., Dr. John W. Duke, Guthrie.

Oregon: Portland, July 7-9. Sec., Dr. L. H. Hamilton, Medical Bldg., Portland.

Rhode Island: Providence, July 2-3. Sec., Dr. Gardner T. Swarts, State House, Providence.

South Dakota: Deadwood, July 14. Sec., Dr. Park B. Jenkins, Waubay.

Texas: Austin, June 23-25. Sec., Dr. W. L. Crosthwait, Waco.

Utah: Salt Lake City, July 6-7. Sec., G. F. Harding, 405 Templeton Bldg., Salt Lake City.

Vermont: Burlington, July 14-17. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 23-26. Sec., Dr. Herbert Old, Norfolk.

Washington: Seattle, July 7. Sec., Dr. C. N. Suttner, Baker Bldg., Walla Walla.

West Virginia: Elkins, July 1. Sec., Dr. S. L. Jepson, Wheeling.

Wisconsin: Milwaukee, June 29. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

Wyoming: Laramie, July 9-11. Sec., Dr. H. E. McCollum, Laramie.

MEDICAL EDUCATION *

Kendric C. Babcock
Dean of College of Liberal Arts and Sciences of the University of Illinois
URBANA, ILL.

No single feature of improvement in higher education in the last seven years better deserves reiterated emphasis and approval than the progress in medical education. The changes of the last year give renewed cause for satisfaction. The continued decrease in the number of medical schools, from 162 in 1906 to 106 in 1913, is fresh evidence of sound appreciation of the vital necessity of most thorough, exacting and scientific training in laboratories, and actual, practical apprenticeship under expert direction in large hospitals.

By the action of the Council on Medical Education of the American Medical Association, acting in cooperation with the Association of American Medical Colleges, a new milestone in the progress of medical education was established in the spring of 1913. Step by step the curriculum of a standard medical school has been extended to cover four years; admission has advanced from the modest requirement of the completion of high-school education to requirement of a preliminary college year, which should include at least physics, chemistry and biology. Forty-three medical colleges at the close of the period covered by this report were enforcing at least this requirement; others have announced that it will go into effect in 1913; still others have signified their intention to put it into operation in 1914. By these schedules there should be after January, 1914, seventy-one medical colleges requiring for entrance one year of college work, including courses in physics, chemistry, biology and a modern language. But this is not the whole story. Thirty of them, including those which require a bachelor's degree for admission, now demand two years of work in a college of liberal arts, in addition to a high-school course covering four years, and nine have announced the adoption of the two-year collegiate requirement, to become effective before the end of 1915.

The Council on Medical Education, by its announcement of the basis on which medical colleges will be rated in the council's classification as "Class A+, acceptable medical colleges," and "Class A, colleges lacking in certain respects, but otherwise acceptable," has fixed and defined this new or collegiate requirement of a single year (The Journal, Aug. 23, 1913, p. 582). This requirement for admission becomes effective on and after Jan. 1, 1914. The Association of Medical Colleges expresses its requirement in slightly different terms—"one year each of physics, chemistry and biology of college grade, each not less than eight hours." While these two associations have no legal authority to compel the acceptance of their standards, the value of the recognition accorded to an institution by placing it in Class A+ or Class A is so great that ambitious institutions cannot afford to defer compliance longer than is absolutely necessary. It should be noted in this connection that the information on which classification by the Council is made or admission to the Association of Medical Colleges accomplished is based on the direct personal examination of the work of institutions listed by an agent or by a committee of these two organizations. The rating, therefore, is not a paper-made affair, but one which commends itself because of its thoroughness and because it is continually kept up to date by visitation, conference and correspondence.

Confronted by the enormously increased cost of maintaining a first-class medical school, the movement to surrender medical education to the state university or to put it under the care of the state has gone on apace during the year under discussion. The medical college of Drake University, Des Moines, Iowa, was transferred by a cordially amicable arrangement to the State University of Iowa; the medical college of Willamette University, Salem, Ore., has been discontinued and all medical education in Oregon will be carried on by the University of Oregon, in Portland. The state of South Carolina has adopted and made appropriations for the Medical College of the State of South Carolina, located at Charleston. An agreement has been perfected by which the University of Alabama will take over the Birmingham Medical College and make of it the postgraduate department of the university's medical school. The College of Physicians and Surgeons of Chicago, which has had an intermittent affiliation with the University of Illinois, without receiving any state aid, however, has recently turned over all its property to the university and gone out of existence as a separate corporation. State aid, which was once defeated by the veto of the governor and once by a decision of the supreme court of the state, seems now assured. The two medical schools in Richmond, Va., the Medical College of Virginia, which has received a small subsidy from the state, and University College of Medicine, which must not be confused with the medical school connected with the University of Virginia, at Charlottesville, have united as the result of long negotiations.

---

* Part of report on Higher Education in Chapter II of the 1913 report of the U. S. Bureau of Education.

The financial resources of the medical schools have shown gratifying increases. State appropriations have been generous both for maintenance and for buildings, while gifts running into the millions for hospitals, for instruction and for endowment of research fill the record of the year. The campaign of the Western Reserve University, of Cleveland, in the past two years resulted in a total of $1,533,000 of endowment for the medical department of that institution. During the past year the University of California received an aggregate of nearly $480,000 toward a total of $600,000 for teaching hospital, and the George William Hooper Medical Endowment, consisting of property valued at considerably more than $1,000,000, perhaps ultimately $2,000,000, for purposes of medical research.

New Rules in Illinois

From Dr. C. St. Clair Drake, secretary of the Illinois State Board of Health, we have received the following notice of an amendment to the rules and regulations relative to the administration of an act to regulate the practice of medicine in Illinois, in force July 1, 1899. The notice is dated May 26, 1914:

Examinations of candidates for state certificates authorizing the practice of medicine and surgery in Illinois will be held in Chicago, in January, May, June and October, as far as practicable, each year.

All examinations will be in writing and will embrace the subjects hereinafter stated, these subjects being covered in ten papers, each paper being made up of ten questions, as per the following grouping: (1) chemistry, etiology and hygiene; (2) physiology and neurology; (3) anatomy; (4) materia medica and therapeutics; (5) pathology and bacteriology; (6) surgery; (7) physical diagnosis, ophthalmology and otology, pediatrics; (8) obstetrics; (9) gynecology, laryngology, rhinology and medical jurisprudence; (10) practice of medicine.

A candidate to be entitled to a state certificate authorizing the practice of medicine and surgery in Illinois must obtain in his examination a general average of not less than 75 per cent., with a rating of not less than 60 per cent., in any one paper, as set forth in the preceding paragraph.

This amendment is to take effect and become operative in all examinations given by the Illinois State Board of Health, after July 1, 1914.

Connecticut March Report

Dr. Charles A. Tuttle, secretary of the Connecticut Medical Examining Board, reports the practical and written examination held at New Haven, March 10-11, 1914. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 20, of whom 14 passed and 6 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Yale Medical School	(1911)	87.2
Baltimore Medical College	(1909) 75.1,	75.6
Johns Hopkins University	(1911) 77 5; (1913)	88.1
Maryland Medical College	(1911) 75.8; (1912) 75.1; (1913)	82.4
University of Maryland	(1912)	81
John A. Creighton Medical College	(1913)	81.7
Albany Medical College	(1894)	77.3
Woman's Medical College of Pennsylvania	(1913)	82.6
University of Vermont	(1912) 77,	81.6
FAILED		
College of Physicians and Surgeons, Baltimore	(1913)	67.5
Maryland Medical College	(1913) 63.3,	65.5
College of Physicians and Surgeons, Boston	(1908)	65 5
University of the South	(1902)	63.5
University of Catania, Italy	(1912)	63.3

Book Notices

A TREATISE ON THE DISEASES OF WOMEN. For Students and Practitioners. By Palmer Findley, B.S., M.D., Professor of Gynecology, College of Medicine, State University of Nebraska. Cloth. Price, $6 net. Pp. 954, with 670 illustrations. Philadelphia: Lea and Febiger, 1913.

This treatise is an outgrowth of the author's "Diagnosis." The subject-matter is divided into thirty-four chapters, arranged in order rather different from that usually employed, which necessitates considerable overlapping of subjects. Yet if we view this fact from the position of the student who is reading the subject for the first time, we shall agree that it is no detriment to have the repetitions. Indeed, it may be a source of advantage. A wide knowledge of the literature is shown in nearly every page, especially in the chapters developed from some of the author's comprehensive papers. It is to be regretted that a bibliography is not given. There is a remarkable freedom from unsupported and dogmatic assertions, and the book is scholarly in tone. A critical examination shows much to commend and little to criticize. The work seems so strong that attention is called to certain points to which we may object with the hope that they may be corrected in future editions of the book.

The chapters on hemorrhage are arranged to give the student a clear idea of the menstrual phenomena. The author, however, like so many others, has incorporated the old myth that the Caucasian race is more subject to carcinoma and the African to fibroids (p. 21). This statement receives but little support (p. 576) where he states that Kelly and Williams, who have had abundant opportunity to make reliable observations, deny that the negress is preeminently susceptible to fibroids. Even were the result contrary, the observation of 357 cases should not permit of conclusions which may be applied to an entire race. It is surprising to note that in the treatment of dysmenorrhea, treatment by stem pessaries is dismissed in four lines of disfavor, while Pozzi's operation, which to some authorities has no fundamental basis whatsoever, is pictured in four three-quarter-page drawings. Incidentally, Findley is not a believer in tents for cervical dilatation, restricting his choice to the Hegar dilators. Fatigue is not mentioned as a cause for backache, and the author apparently believes that douching will cure leukorrhea—thus marring, to some extent, a very good chapter.

The chapter on sterility shows breadth of view. The effect of acid secretions is considered; extract of corpus luteum is advised in the artificial menopause. A chapter on the examination of the blood is wisely inserted, yet on first glance would appear to be unnecessary in a work of this type. The same statement applies to the chapter on the microscopic examination of scrapings. A valuable chapter on non-operative methods of treatment precedes the preparation for operation. Massage and pressure therapy are discussed quite fully, and organotherapy and serum therapy have a page. Polak's results in the treatment of pelvic infections with vaccines are quoted as encouraging. The absence of diagrams illustrating the method of replacing a retroposed uterus both in the description of non-operative methods and in the discussion of retroversions is to be regretted. They would seem quite as valuable to the student as the illustration of the man in an undershirt painting iodin on an abdomen (p. 245). The author uses Schleich's solution for local anesthesia. The method of putting on dry sterile gloves is splendidly shown on page 253. This is a most valuable illustration and one which could be shown (unfortunately) to the majority of operating-room nurses to the benefit of their technic. How often nurses, in holding gloves for the operator to thrust his hand into, manage to touch the bare hand and thus (frequently) contaminate their gloves! At the same time the illustration on page 274, which depicts one finger in the urethra and the other in the rectum to demonstrate an atresic vagina, should be condemned. At present, methods which demand the insertion of a finger into the urethra have no place in modern gynecology. Unfortunately the students frequently remember the illustrations longer than the text, and some novitiate will undoubtedly attempt such a barbarous procedure. With this exception, the difficult subject of anomalies of the vagina and uterus is ably handled. The order of presentation of the displacements of the uterus does not appear logical, even though it has the authority of like arrangement in several Scottish and English texts. Retroversion with descent is the natural prologue of procidentia and is best considered before it. The discussion of the various postures which a displaced uterus may assume is not wisely inserted, as it is apt to confuse the student so that he remembers the details rather than the principles. It is only fair to say, however, that in comparison with many American texts the discussion of retrodisplacements here given is simplicity itself.

Findley advises the Todd-Gilliam operation, as well as the Webster, the illustrations of which (Baldy) do not show the ligaments spread out fan-shape on the back of the uterus as they must be to prevent recurrence, and indeed as they are described in the text. In the chapter on inflammation of the uterus the author appears committed to the older nomenclature. Thus he describes many erosions (non-cancerous) which would be far better described as what they really are, eversions, and appears unwilling to accept the splendid work of Hitchman and Adler at its face value. Therefore, he gives a clinical and anatomic classification of endometritis, and in the latter retains the old divisions of Ruge and Veit. The treatment of puerperal infection is well given. He does not use the curet, and does not recommend hysterectomy. He does stimulate with strychnin, and does not suggest the need of obtaining rest and sleep, with opium if necessary, nor does he suggest outdoor treatment.

Findley still uses Noble's compilation of 2,274 cases to enforce his arguments. He quotes the much-quoted statement of Bayle, misspelled in the text as Boyle (p. 576), that 20 per cent. of women more than 35 years of age have fibroids. This statement made prior to 1813 cannot be traced beyond the point where Bayle, in an article in the Dictionnaire des sciences médicales, says in making the necropsy on 100 women of more than 35 years in age, 20 per cent. will be found to have fibroids. It is time we dropped such loose statements from our literature.

This work, which combines safe treatment and scholarly consideration may be commended as one of the best volumes of its class in recent times. The publishers also deserve congratulation, as they have done their part well in the preparation of an interesting text.

Grundsatze für den Bau von Krankenhausern. By Obergeneralarzt Dr. Thel, Inspekteur der 5. Sanitatsinspektion. Second Edition. Paper. Price, 6 marks. Pp. 170, with 88 illustrations. Berlin: August Hirschwald, 1914.

The title of this book indicates that the author is attempting to set forth the principles to be used for the planning and construction of hospitals. It is illustrated with a number of plans of existing institutions and detail plans of operating departments and isolation buildings. The larger plans illustrate German military hospitals which do not contain arrangements of particular value to Americans. The work begins with an interesting history of hospitals. It contains a number of tables in regard to the number of hospital beds in European cities, the cost per bed of many well-known hospitals, areas of buildings per bed, the division for different services and other statistical matters, all of which are taken from larger works such as "Das Deutsche Krankenhaus" by Prof. Dr. Grober; but those who do not possess this work will find the smaller one helpful and reasonable in price. The book does not treat of the management or organization of hospitals and is intended more as a guide to builders. Inasmuch as the author is not an architect or builder his advice in regard to building matters is not technically correct in many instances, and is also incomplete. The illustrated method of deafening floors cannot be used in this country. Some recommendations appear unusual to Americans; for instance, "gas-pipes are to be placed on wall and ceiling surfaces. They are not to be placed within the mason work, so that leaks can be found easily and repairs made quickly." This does not speak well for German pipe installations, for such troubles are exceedingly rare in American cities.

Two statements by Dr. Thel appear particularly noticeable, namely: "Building good hospitals without possessing great experience is not possible in this specialty." "The experience frequently employed by communities in appointing commissions for the building of hospitals, who may make an inspection trip for the purpose, but who have little experience in this field, is a poor method to proceed with the construction of a hospital." The author also calls attention to the necessity of the proper attention to ventilating apparatus by saying, "The help and nurses must be fully instructed in regard to the ventilating apparatus in order that it obtain proper attention and good operative results; the help and nurses must be watched continuously in this matter." That the Germans persist in their contention that hospitals should not have many stories is shown by Dr. Thel's statement that a height of two stories should be exceeded only in exceptional cases.

Diagnostic Symptoms in Nervous Diseases. By Edward Livingston Hunt, M.D., Instructor in Neurology, College of Physicians and Surgeons. Cloth. Price, $1.50 net. Pp. 229, with 54 illustrations. Philadelphia: W. B. Saunders Company.

This was written to supply the demand for a manual containing the salient points and leading symptoms of the principal nervous diseases without the laborious search involved in consulting larger text-books. The author has carried out his purpose admirably, and has furnished in a concise, yet readable and entertaining manner, a complete cross-index, so to speak, to the regular text-books. All important symptoms and signs are taken up, with the methods of eliciting them, and a list of the diseases in which they are encountered. The constant use of such a book will enable any physician with a reasonable knowledge of the fundamentals of neurology to avoid errors and to make his own diagnoses correctly in a great many cases which he otherwise could not disentangle without a consultation with a specialist.

This little book, together with one standard text-book, will meet the every-day needs of the student and practitioner better than a whole shelf of large works.

Diseases of Children. A Manual for Students and Practitioners. By John McCaw, M.D., R.U.I., L.R.C.P., Senior Physician, Belfast Hospital for Sick Children. Cloth. Price, $3.50 net. Pp. 524. New York: William Wood & Co., 1914.

This is an effort to put the subject of diseases of children in such a form that busy practitioners and medical students will grasp it readily and be encouraged to go further in the study of pediatrics. It appears to be an eminently fitting book. While the subject-matter is condensed, it is well systematized and the important points are well brought out. More than any other book which has come from the British Isles, it shows a definite knowledge of the work which has been done by Americans and gives full credit for it. The chapters on infant feeding are well written, and while no attempt is made to recommend methods, many are described properly and the practitioner left to take his choice. The chapters on diseases of the respiratory tract, are especially complete and practical.

Diagnostic Methods. A Guide for History Taking, Making of Routine Physical Examinations and the Usual Laboratory Tests Necessary for Students in Clinical Pathology, Hospital Interns and Practicing Physicians. By Herbert Thomas Brooks, A.B., M.D., Professor of Pathology, University of Tennessee, College of Medicine, Second Edition. Cloth. Price, $1. Pp. 82. St. Louis: C. V. Mosby Company, 1914.

Laboratory methods are clearly described in this convenient handbook and so far as a somewhat thorough investigation has shown, it is reliable.

Miscellany

Combined House and Office for the Physician

In *Suburban Life*, for May, Charles Vaughan Boyd discusses the building of a distinctive type of combined residence and office for the physician. Generally speaking, the house is composed of two units, represented by the family quarters and the service department. In a physician's residence, three units are necessary on account of the requirements of office space. In planning such a residence for the physician, care must be taken not to place undue emphasis on any one portion. The pleasure of the family cannot be ignored in locating the living-rooms, nor can the welfare of the servants be overlooked. It is also not wise to relegate to inconspicuous position the rooms actually devoted to the physician's office. It is therefore believed that the best location for such a residence is at the intersection of two streets. By this procedure, the house gains in two important details: First, there is assured an abundance of light and air. Second, there is provided an equally desirable position for the family entrance and the office entrance.

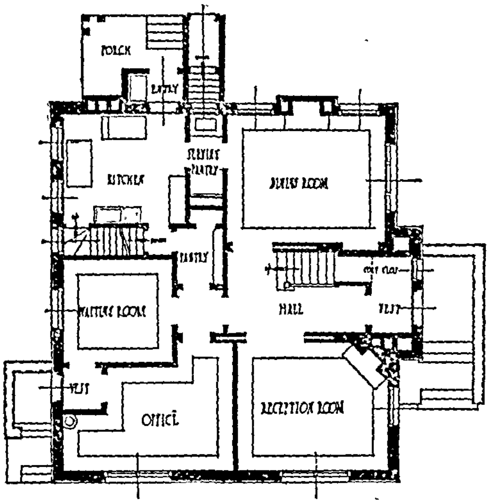

Fig. 1.—Combined house and office at Hamilton, Canada. For description see text.

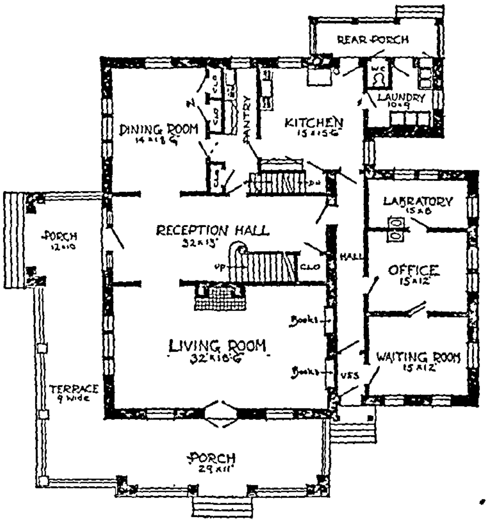

Fig. 2.—Residence and office at Ambler, Pa.

Figure 1 represents the ground floor of a physician's house in Hamilton, Canada. It is located on a corner, the house and the office being entered from different streets. The office entrance, it will be seen, is not at the front of the house. A small vestibule serves as means of communication with both the waiting-room and the office. Each of these rooms is also connected with an inner hall which, in turn, is connected with the living and service quarters. In this plan, only two rooms are allowed for the office, the waiting-room and the consultation-room. The plan, however, is very compact and permits of a convenient arrangement of the living-rooms. In this house, a large living-room is provided on the second floor, which overlooks the intersecting streets.

Figure 2 is the plan of a residence and office at Ambler, Pa. It represents the remodeling of an old house, the office wing being added. It has a separate office entrance at the front of the house. The plan as a whole, if not particularly well balanced, affords a convenient arrangement of the office which consists of waiting-room, consultation-room and laboratory with a separate hallway running the length of all these rooms and affording entrance to the kitchen. The office hall communicates with the reception hall of the residence. The hall running the entire length of the office rooms permits patients to leave the consultation-room without reentering the waiting-room.

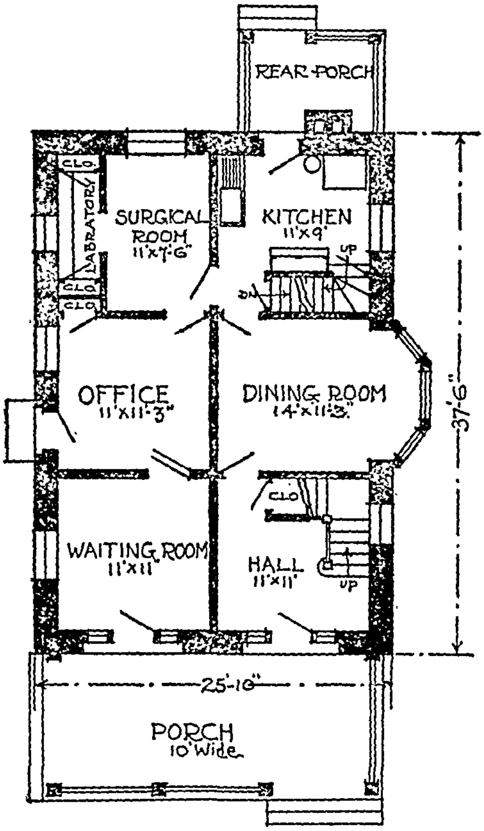

Fig. 3.—Combined office and house at Fort Washington, Pa.

Figure 3 represents a Fort Washington, Pa., house, showing the office and residence portion well isolated in a plan of small area. The office portion has three conveniently arranged rooms, the waiting-room in front, consultation-room next, and surgical-room at the rear which connects with the kitchen. The surgery also has connected with it a laboratory. Plenty of closet room is provided in both consultation-room and surgery. This office does not allow of the exit of the patient without going through the waiting-room, but slight changes in the plan would remedy this. In this plan the living-room would again have to be placed on the second floor, as only hall, dining-room and kitchen are provided for on the first floor.

Figures 4 and 5 represent arrangements which would prove convenient for houses fronting two streets. Only two rooms are provided for office purposes. In these plans the living-rooms are all on the first floor, which, of course, necessitates a larger house.

Figure 6 is the plan of a large house at Melrose, Pa. The feature of this plan is the reception hall between the waiting-room and the office, which would perhaps afford greater privacy in the consultation-room but less convenience in the handling of patients. The kitchen is placed back of the office rooms, and in the dining-room must be entered through a pantry which is more or less desirable according to the point of view. This is an elaborate and expensive house. The office and residence portions are well isolated.

Cultivation of Camphor in Formosa

The staple industry of the island of Formosa is the cultivation of camphor, the exports of which during 1912 advanced from 6,613,700 pounds, worth £354,100 ($1,720,926), to 8,649,300 pounds, worth £553,600 ($2,690,496). The principal importing countries were the United States, with 2,370,300 pounds; Germany, with 2,243,400 pounds; Japan, with 1,694,000 pounds, and the United Kingdom, with 1,003,000 pounds, while France, India and Austria also took considerable quantities. In view of apprehension as to gradual exhaustion of camphor forests in Formosa, considerable afforestation schemes are under way. From 1913 about 3,000 acres annually for twelve years are to be planted with young trees; the cost for the first year is placed at about £11,800 ($57,348). The development of the mountainous interior and the gradual subjugation of the savage territory are stated to have disclosed new camphor districts which are being carefully investigated and preserved for future use. It is considered that the camphor resources of the island will be equal to all future demands.—*Australasian Med. Gaz.*

Indigent Consumptives in the West

The expense and the care of poverty-stricken consumptives sent to certain portions of the West and Southwest by physicians or friends is a heavy burden on the taxpayers of those communities. Many arrive with insufficient funds to support them for even a short time and become public charges. It has therefore been proposed to provide hospitals for such persons by federal legislation. A bill is now before congress known as the Shafroth-Callaway bill which provides for the use of abandoned military reservations and other government property in the Southwest as hospitals for such patients. These are to be operated under the direction of the United States Public Health Service. The bill also provides that the tuberculosis hospital at Fort Stanton, N. Mex., may be used for the care of consumptives who have contracted their infection in another state and are a menace to interstate commerce. As an indication of the burden these cases may become, it was found that in one Texas city during twenty years there were 6,959 deaths from tuberculosis, and 33 per cent. of these persons had been residents of the city less than six months, and a much larger percentage residents less than three years. As an amendment to the Shafroth-Callaway bill it has been suggested that a certain percentage of the cost of maintaining an indigent consumptive should be charged against the city or county from which he comes. This would discourage sending such patients away as could be cared for more cheaply and as well at home. It would also stimulate the establishment of local hospitals.

Medicolegal

No Evidence of Malpractice in Treatment of Eye

(Phebus vs. Mather (Ill.), 181 Ill. App. 274)

The Appellate Court of Illinois, First District, affirms a judgment for the defendant in this action for alleged malpractice in the treatment of an eye. The court says that the plaintiff testified that, after her right eye had been a little inflamed for three or four days, which she attributed to a cold, and she had got a cinder or something in her left eye, she went to the defendant's office, after which the eye continued to get rapidly worse; that he scraped around it with a wooden toothpick, and two days later he told her she must go to the eye and ear infirmary. She also testified that on the occasion of the use of the toothpick her mother had said to the defendant that if he did not think he could cure the eye she would send the plaintiff to a specialist, to which the defendant replied that it was nothing serious and that he knew his business. The defendant, on the other hand, testified that the first time he saw the plaintiff's eye he advised her to go to a hospital, it being apparent that she was suffering from purulent ophthalmia, caused by a gonorrheal infection. It also appeared from the evidence that at that time the plaintiff's husband was suffering from gonorrhea. The law seems to be well settled that in order for the plaintiff to recover in a case of this character it is incumbent on him to prove that the treatment administered by the defendant was negligent or unskilful, and also that the alleged injuries were the result of such treatment. The general rule also is that mere proof that a good result was not obtained is, of itself, no proof or evidence of negligence or lack of skill, of which, and of the fact that the injuries complained of resulted therefrom, there must be affirmative proof. Usually, and especially in eye cases, such proof can be established only by the testimony of experts skilled in the medical profession, and cannot be made by lay witnesses. Nor does the court think that a question for the jury was raised by the testimony of the physician who treated the case at the infirmary, that he thought there would have been a better chance had the case come earlier under his care, but he did not know whether the eye could have been saved. To permit a jury of laymen to speculate as to what result that "better chance" might have produced was clearly improper, especially in view of the expert physician's statement that he had no opinion on that subject. There was no competent testimony tending to show either negligence in the treatment by the defendant, or that the injury complained of was the result of such negligence.

Compensation for Volunteered Emergency Services

(Schoenberg vs. Rose (N. Y.), 145 N. Y. Supp. 831)

The Municipal Court of the City of New York, Borough of Manhattan, Sixth District, says that during the trial of an action against a corporation the president thereof while testifying fell from his chair unconscious. The plaintiff in this case, a physician making a specialty of treating the eyes, ears, nose and throat, being in attendance as a witness for the other side, volunteered his services, and, with another physician similarly present, sought to restore respiration, but finally pronounced the man dead. The president left a large estate, and each of the physicians presented a bill for $500, but the court adopts the value placed on the plaintiff's services by the executors' experts and gave him a judgment for $15, which it considers the reasonable value of such services, the latter not being difficult.

The court says it is of the opinion that, while the financial condition of a patient does not alone affect the abstract question of the value of a physician's services, it is a proper element entering into the question as to what charge or what reduction in the charge shall be made by him by reason of such financial condition. So a patient of no means, or of limited means, may prove that his circumstances and station in life are such as to render a physician's charge exorbitant and out of all reason and proportion to the patient's ability to pay, while the same charge to a person of large means would not be considered unreasonable. The financial condition of a patient is an element that it may be assumed is considered by both physician and patient when the services are contracted for, rendered, and accepted, and may also be considered by the court in determining the reasonableness of the charge; and that element should apply to a case in which there is and was no contract, but a mere fiction of law creating one, else, in a case where services are rendered to an unconscious man who never recovers, the charge against his estate might be so great and unreasonable as to be out of all proportion to the value of the estate.

This court is unable to draw a distinction as to the right of recovery between a case in which the physician is called by a stranger or spectator and one in which he proceeds to treat a person while unconscious, or *in extremis,* without being asked to do so. The right to recover in both cases is the same, and the argument to support such right could be carried to great length. In the court's opinion there is an implied contract in both cases, and, if the physician chooses to stand on his legal rights to recover, he is entitled to enforce those rights and must receive what his services are reasonably worth, regardless of what may be considered the ethics of the medical profession in such a case, with which the court is not concerned. When duty requires the physician to give his aid, and he has given it, he may expect payment by reason of the promise created by law from the patient to do so, although the patient never asked for the aid or consented to it being given. In an emergency case, requiring immediate attention to save life, the physician when called, or when he volunteers his services, should not stop to inquire by whom he will be paid, or to make it known that he expects to be paid. It would be inhuman to do so or to give the subject a thought. Offering his aid does not establish the fact that he intended his services to be gratuitous. Whether or not he did offer aid is a question of fact.

Authority for Physical Examination Does Not Include Taking of Roentgenograms

(Lasher vs. S. Bolton's Sons (N. Y.), 146 N. Y. Supp. 321)

The Appellate Division, Third Department, of the Supreme Court of New York, reverses an order directing the plaintiff, a female infant, who was seeking to recover damages for personal injuries, to submit to the taking of a roentgenogram of her right foot. The court says that the plaintiff, through her attorney had consented that a physician might make a physical examination of the foot in behalf of the defendant, and later the order reversed was granted. The court is clearly of the opinion that there is no foundation in law for the order. The examination of witnesses before trial is purely statutory, and authority for a physical examination of a party to an action does not include authority to take photographs or roentgenograms, especially when the defendant has already, by consent of the plaintiff, had the advantage of a physical examination. The general purpose of the statute was to change the rule of the common law, and under well-established rules the authority is not to be extended beyond the clearly expressed intention of the statute. The statute expressly provides that, in the event that the person to be examined is a female, she shall be entitled to have such examination before physicians or surgeons of her own sex, and this rule is not limited to adult females but applies to all females. The order here under consideration simply directed a particular physician, a man, to take a roentgenogram of the plaintiff's right foot, though it appeared from the record that the physician was not a roentgenologist, and the order seemed to contemplate that it should be actually taken by some other person, for it was to be done under the direction of this physician, who was not authorized under the rules of practice to act as a referee, and who had, according to the language of the order, "already made a physical examination of the infant plaintiff for and on behalf of the defendant."

Purpura Annularis Telangiectoides

Dr. George M. MacKee, New York: This affection attacks young male adults, although two cases have been noted in infants. The eruption is always situated on the anterior and lateral surfaces of the lower limbs, below the knees, with occasional lesions above the knees and on the arms, and very rarely on other portions of the body. The appearance of the eruption is nearly always preceded by rheumatic pains. Otherwise there are no subjective symptoms. The disease is divided into three fairly well-defined stages: first, telangiectatic; second, purpuric and pigmentary, and, third, atrophic. Regarding the differential diagnosis and etiology, many cases give a positive tuberculin reaction, but at the same time many do not. Inoculation experiments have been negative. These facts, together with the clinical and histologic pictures, would seemingly rule out the possibility of tuberculosis. Occasionally, in syphilis, an annular purpuric rash is present, which is due either to the syphilis or possibly to the mercury. This eruption is usually limited to one small area, is evanescent in character and disappears without atrophy and with temporary pigmentation. The etiology of the disease is unknown, but is thought to be either a neurosis or a reaction to some toxic substance. It can be differentiated from any known dermatosis, and is undoubtedly an entity.

DISCUSSION

Dr. A. Schalek, Omaha: Whatever this skin disease may be, I certainly do not think the name purpura a good one. It does not agree with any of the characteristics of purpura as we know them.

Dr. A. Ravogli, Cincinnati: It is a beautiful thing to place new names and to try to designate diseases of rare quality by these new names, but we must remember, too, that we have acne necrotica and tuberculids, but whether they have just the same formation of pustule with resulting scar as that described by Dr. MacKee, I do not know.

Dr. W. H. Mook, St. Louis: I have seen four or five of these cases in the last seven years, and placed them under the classification of atrophic dermatosis of unknown origin. One of the cases had quite an ulceration, about the size of a dime, that existed for something like two years, and refused to heal up with any sort of treatment.

Dr. M. F. Engman, St. Louis: My attention was first called to this condition several years ago by Dr. Mook, and since then I have seen several cases and have called them "Mook's disease." Then, in looking over the literature about six or eight months ago, I came across some articles about this disease. Most of the cases reported in the literature occurred in railroad men and those who were on their feet a great deal.

The Abderhalden Technic as Applied to the Diagnosis of Syphilis

Dr. H. R. Varney, Detroit: From seventy-five cases examined experimentally the following conclusions are drawn: The specificity of the Abderhalden technic applies to syphilis. Syphilitics have in their blood-serum enzymes which react with the protein of the organism. Tissue derived from active human lesions is more specific than syphilitic tissue of the rabbit. Mixed infection in the human lesion gives rise to error, as shown in our cases of sinus disease, furunculosis, etc. Further work will be required to determine whether all syphilitics have the power of developing ferment, and at what stages of the disease the test is present or absent. We believe that polyvalent antigens prepared from several strains of pure culture of the spirochete offer the best hope for further success with this technic. The degree of success with the test varies in proportion to the care and precision exercised in its execution.

DISCUSSION

Dr. Udo J. Wile, Ann Arbor, Mich.: I have undertaken some experiments with the Abderhalden technic in another condition this year, and it was a most difficult technic to carry out. At least, I found it so. The specificity of the spirochete antigen is extremely interesting, in view of the specificity of the test in this as well as other diseases.

Dr. H. R. Varney, Detroit: The Abderhalden technic is easy as compared with the original Wassermann, in my opinion.

A Study of the Spinal Fluid with Reference to Involvement of the Nervous System in Secondary Syphilis

Dr. Udo J. Wile and Dr. John Hinchman Stokes, Ann Arbor, Mich.: A large proportion of all patients in the secondary period of syphilis, in our series 63 per cent., showed evidences in the spinal fluid of the involvement of the central nervous system. From the special examinations made, we must conclude that this does not represent the whole number who will at some time show, or who have already shown, a reaction on the part of the central nervous system. The absence of findings indicative of meningeal reaction in a single examination cannot be taken as conclusive evidence of freedom from central nervous involvement. Any of the findings, lymphocytosis, increased albumin and globulin content and positive complement-fixation test, may be present alone or in varying combinations, and each indicates involvement of the central nervous system. Comparing this high ratio of early involvement with the relatively low ratio of later involvement, as compared with the total number of syphilitics, we must conclude that the early involvement is mainly a transitory manifestation. The central nervous system is particularly likely to show involvement in cases in which the eruption is papular or follicular in type. Marked subjective symptoms, such as headache, insomnia and nervous irritability, were usually accompanied by positive findings in the fluid in our series. In a general way, cases in which there had been little or no treatment showed a higher percentage of involvement than those in which vigorous treatment had been inaugurated. Involvement of the central nervous system was found in a relatively high percentage of those cases in which the general health was considerably affected. The commonest finding indicative of meningeal reaction was the increased globulin and albumin content, the positive Wassermann ranking next, and lymphocytosis last. As an aid to diagnosis and as a possible guide to prognosis, the value of the spinal puncture in cases of secondary syphilis can scarcely be overestimated.

DISCUSSION

Dr. J. A. Fordyce, New York: I have for a long time been convinced that there are various strains of the spirochete, and that there is a strain that has a special predilection for the nervous system. Dr. Nichols of the Army Medical School of Washington has recently published a very suggestive article on a strain of spirochete that has a given infective power. He has studied the biologic characteristics of this organism, and I think has pretty definitely shown that there is a spirochete which has a predilection for the nervous system. The majority of neurologists believe that there are not more than from 5 to 10 per cent. of syphilitics who show involvement of the nervous system. If a larger percentage than that show involvement in the early stage of the disease, as Dr. Wile has said, it must be a passing infection, a hyperemia of the meninges, which passes off. I have been making a study of the spinal fluid in late syphilis, in tabes, paresis and various forms of cerebrospinal syphilis for the past two years, but in the last three or four months I have examined the spinal fluid in about thirty cases in various stages of the secondary period of the disease, for the globulin content and lymphocytosis, as well as for the Wassermann reaction. I started out firmly convinced that we should find from 40 to 50 per cent. of involvement of the nervous system, but to my surprise have found it considerably smaller than that. Repeated punctures should be made in the same case, as the fluid may be negative this week, and a month later positive. We should make the examination in the later period of the secondary stage, and especially after treatment with salvarsan. One, two or three injections of salvarsan are apt to develop a latent reaction in the fluid, and you are more apt to get changes after the patient has been under treatment for some time.

Dr. J. F. Schamberg, Philadelphia: Dr. Wile's studies show us with what frequency the nervous system is involved, often at a very early stage of the infection. It is necessary to study not only the blood in these cases, but also the cerebrospinal fluid, in order to prevent later disastrous results affecting the nervous system.

Dr. Udo J. Wile, Ann Arbor, Mich.: I think, as Dr. Fordyce says, that most of these nervous conditions are transitory phenomena, and that for the most part energetic treatment directed to the general syphilis serves to clear up the syphilis of the central nervous system. It is impossible to say just how many of these cases in which the cerebrospinal system is early involved become our late cases of tabes and paresis, or as to whether or not they fall into this group. It is highly probable that of this number 5 per cent. are drawn from these cases of early involvement.

The Use of Calcium Lactate in the Treatment of Certain Dermatoses

Dr. Charles J. White, Boston: Believing that calcium had shown decided curative powers in certain instances, I decided to make a thorough therapeutic trial of the drug. I have prescribed calcium in many different conditions, but by elimination of the unsatisfactory tests the final trials have been limited to the following diseases and conditions: hyperhidrosis, pernio, herpes simplex, erythema multiforme, urticaria, livedo, purpura and angioneurotic edema. In addition to the calcium salts, patients have been asked to partake as freely as possible of food rich in calcium, and have been urged to avoid raw fruits and all acid foods, for it has seemed to me that many persons suffering from the suspected diseases have been large consumers of these articles of diet. External treatment has been prescribed in all cases, a factor which vitiates the scientific value of the whole work, but it must be borne in mind that most of these patients were referred by general practitioners who had been unsuccessful in previous treatment, and, furthermore, that these patients were mostly wage-earners who deserved as speedy restoration to health as was possible. Also, the work was necessarily hampered by the fact that all these patients were ambulants, who obey or break laws as the spirit moves them. In summing up my experiments, I think it seems fair to state that calcium is certainly not a specific for any of the diseases mentioned in any sense of the word, but it is a drug which may render distinct and most welcome service in any one of them, and a drug which should always be tried in obstinate examples of the conditions above cited.

DISCUSSION

Dr. W. A. Pusey, Chicago: Ever since Wright began to hypnotize us with his fascinating theory, I have been interested in the coagulation time of the blood and the use of calcium salts in the conditions suggested by Wright. I have made it a plan for many years in cases of such intoxications as urticaria, erythema multiforme, purpura and chronic eczemas to make a routine coagulation-time test, and I first became disappointed in that. I have never been able to make out any distinct characteristic relationship between the coagulation-time and the occurrence of any of these conditions, so that I had no delayed coagulation-time as a basis on which to use calcium salts. I used calcium salts for many years in the intractable cases of this sort, especially urticarias, erythema multiforme and intractable eczema, and then let it fall into disuse. Then I took it up again, and must confess to having had practically no evidence of its value. I first used calcium chlorid and later calcium lactate. If Dr. White, however, who is such a careful observer, has found calcium lactate useful in such an intractable condition as hyperhidrosis, I am going to try it again.

Dr. M. B. Hartzell, Philadelphia: I have tried the calcium salts extensively, and regret that I have yet to see a single instance in which I thought my patient had been benefited in the remotest degree. Still, one man's experience does not count for very much, and I shall take renewed courage and try it again.

Dr. D. W. Montgomery, San Francisco: I have given calcium lactate in a very interesting case of erythema multiforme due to the *Bacillus coli communis,* and obtained no appreciable amelioration of the symptoms. I have not tried the drug in hyperhidrosis, but I should think, from the vast number of causes of hyperhidrosis, that it would be problematic if it would do good; but it is all a chance, and we might do good by using it.

Dr. David King-Smith, Toronto: Calcium lactate has been tried in various conditions in the hospital with which I am connected, not only in dermatologic cases, but others as well, and I think I may say that it has been rather disappointing. Probably the best results are obtained, however, when the drug is given in 20-grain doses three times a day, for two days, then stopped for two days, and then repeated for the six doses; if it is going to do any good, as a rule, it will have done it then.

Dr. Charles G. White, Boston: I have also had a good many failures in the use of this drug, but have had better success than those who have discussed my paper. I do not think the giving of the calcium lactate is the whole thing. You must cut out the acids and give foods that contain calcium, and, above all, you must stop the use of magnesium at the same time. The two drugs are opposed in their results, and many failures have come because you are giving magnesium to clear up the bowels, and calcium with the idea of curing the disease. They neutralize each other and you get no effect.

NEW YORK ACADEMY OF MEDICINE

Meeting Held April 16, 1914

The President, Dr. William M. Polk, in the Chair

Medical Aspects of Treatment of Pyloric Stenosis in Infancy

Dr. L. Emmett Holt: In my series of 57 cases, 52 were breast-fed infants; of these 40 had nothing but the breast and 12 had mixed feeding. Hence bad feeding can scarcely be invoked as a cause of this condition. Of 55 cases in which the sex was noted there were 49 males and 6 females. The mortality was 55 per cent.; 28 patients were operated on, with 14 deaths; 29 cases were treated medically, with 17 deaths. The whole crux of the question between medical and surgical treatment of pyloric stenosis seems to be: Are the symptoms and condition such as to make it probable that the patient will or will not live long enough for the pathologic condition to subside? There are medical as well as surgical risks. The indications for operative treatment are (1) no diminution of the vomiting or the gastric peristalsis by stomach washing and diet; (2) a steady loss of weight of 1 or 2 ounces a day; (3) marked gastric retention;

and (4) absence of fecal stools. My greatest regret is that operation was delayed in so many of my cases and in some was not done at all. To persist with medical treatment week after week when forcible vomiting and marked peristalsis persist and when the weight shows only a slight loss, seems to me to be incurring far greater risk for the child than with operation.

Pyloric Stenosis in Infancy Treated by Gastro-Enterostomy

Dr. William A. Downes: My series embrace 21 cases, 16 males and 5 females. Seventeen were breast-fed entirely; 3 were partly breast-fed and partly bottle-fed, and 1 was bottle-fed. A typical posterior gastrojejunostomy was done in all the cases. I offer the following conclusions: 1. Hypertrophic pyloric stenosis is congenital to the extent that there is an increase in the thickness of the circular muscular fibers at the pylorus. The presence of this thickened muscle-fiber reduces the lumen of the pylorus; therefore, the stomach in order to empty itself contracts more forcibly than normal. This soon causes the mucous membrane to become thickened and edematous, and to assume a more or less spiral arrangement as it passes through the narrowed pyloric channel of from ½ to ¾ inch. The result is a valvular action which gradually produces complete closure of the pylorus. The question as to whether or not the pylorus will admit a probe or catheter at operation or necropsy is of little consequence when weighed against the clinical evidence of complete obstruction. 2. There can be no doubt that there is sufficient time between the onset of symptoms and the appearance of complete obstruction for careful observation and the carrying out of any medical measures likely to prove of benefit, provided, of course, that the early symptoms have been properly interpreted. The fear, however, that the condition may have existed longer than has been suspected, and that the vitality of the baby is not so good as appearances would lead one to believe, make me feel that operation is indicated in every case of hypertrophic stenosis as soon as the diagnosis is made. Should depression or early evidence of shock be present, immediate operation is demanded. 3. The babies coming to operation in good condition suffer little or no shock, their convalescence is straightforward, and they are at once restored to normal health. My experience in this respect corresponds with that of other operators.

DISCUSSION

Dr. Charles L. Scudder, Boston: It has been demonstrated that the medical treatment by feeding and by drugs in true cases of tumor stenosis has not been satisfactory. If there is a true tumor present, the sooner surgical measures are instituted the better for the immediate condition and the better for the future of the baby. Cases of stenosis not due to tumor are supposed to be occasioned by a certain degree of pyloric spasm. The tumor cases of obstruction are real mechanical obstructions. The tumor occludes the lumen of the pylorus, and it is probably of congenital origin. Quite recently there was reported one case of a new-born baby in which there was a congenital pyloric tumor. This fact is of considerable importance in the proof of the congenital origin of this tumor. The contrast between the rapid improvement in weight, in general appearance, in growth, and in general development in the cases of pyloric tumor operated on and those cases experimented on by feeding and drugs is so great that one can hardly understand the attitude taken by certain medical practitioners who advocate long experimental feeding in true tumor cases. When the diagnosis of congenital pyloric stenosis is made in these little babies, the earlier surgical measures are instituted the more rapid will be the recovery from the emergency starvation and the more sure will be the saving of the life of the child. Children with only partial obstruction will develop symptoms later than those with more complete obstruction. Children with almost complete obstruction will demand surgical interference earlier than those with less obstruction. In the group of cases in which the diagnosis is doubtful, that is, in that group of babies difficult to feed, it will always be justifiable and proper to experiment for a limited time with skilled feeding in order, if possible, to arrive at a satisfactory diagnosis. I believe that comparatively few cases of so-called pyloric spasm without the presence of a true tumor will require surgical treatment.

Dr. Henry Koplik: There are patients who will recover without operation. Patients with a hard palpable tumor should be operated on as soon as possible. Peristalsis is not an indication for operation; many patients have peristalsis and recover without operation. In others there is peristalsis long after recovery. Some cases present marked peristalsis and are very mild in their course. On the other hand, the amount of stenosis is very important as well as the knowledge of just how much food passes through the pylorus into the duodenum. When no great amount of food passes through the pylorus, the sooner the operation the better. I do not agree that all cases should at once be handed over to the surgeon.

Dr. H. M. Richter, Chicago: Could we agree as to the underlying pathologic condition it would be easier to decide what course to pursue. Among my 24 cases, 19 were diagnosed before operation as hypertrophied pylorus with resulting obstruction, and in 5 cases the diagnosis before operation was spasm. Of the 19 cases, 18 showed a palpable tumor before operating. In the 19 cases there was in each a definite fixed hard tumor. In 5 cases a diagnosis of spasm was made on the basis of the peristaltic waves of the stomach and the starvation stools. The underlying pathologic condition, however, is surely quite different from that found in the cases showing hypertrophy, and probably does not constitute an entity, but is variable. There is a definite intestinal obstruction in the true hypertrophic cases. The mortality of gastro-enterostomy is high, but it is being gradually lowered. The results published show that the death-rate is being lowered continuously. Operative treatment, carried out sufficiently early, enables the breast-fed infants to be saved. The duration of treatment in the non-surgical cases is prolonged, and in a large proportion of these cases the mothers lose their milk.

Dr. Howard Lilienthal: I have noted that the location of the tumor in these infantile cases is exactly at the pylorus. The pyloric veins appear at or near the central part of the mass. I have operated in five cases. Two patients died, one from hemorrhage following operation on the mastoid which had to be performed three days after the gastro-enterostomy, the other from some error in technic which resulted in a breaking down of the wound.

Dr. Linnaeus E. La Fetra: My personal experience with this condition comprises fourteen cases. They can be divided into two groups: (1) those in which spasm alone, or spasm with more or less hypertrophy, is a prominent factor; and (2) those with spasm and hypertrophy in which the hypertrophy is or becomes the most important factor. It is altogether possible that the cases change from one group to the other, the long continuance of the spasmodic attacks inducing an increase in the hypertrophy. In all the severe cases more or less hypertrophy is present. Also it is probable that the presence of an original hypertrophy which might be small in amount results in spasm which increases the hypertrophy. Of the cases in the first two groups, those of spasm alone or spasm with some hypertrophy, there were eight patients. All of these recovered without operation except one. The one patient that died had a severe spasm with marked peristaltic waves, but no tumor. Necropsy showed a normal pylorus. Of the cases in which hypertrophy was the prominent feature I have had six; five of these patients were operated on and four died. I should consider that operation is absolutely indicated as the only hope for recovery in all cases in which hypertrophy is the prominent feature.

Dr. Ellsworth Eliot: I think we are all agreed that irrespective of pathologic conditions the cases can be divided into three groups: (1) cases which are mild in their course and amenable to medical treatment, and which are under the care of the pediatrician; (2) the hopeless cases that come to the surgeon in the later stages of the disease; and (3) the doubtful cases in which one is undecided as to the propriety of continuing the medical treatment or resorting to surgical measures. I am quite willing to depend on the pediatrists and to be guided by their advice.

Dr. Alfred F. Hess: I have seen about twenty cases of spasm of the pylorus. We have to deal with two groups of cases: (1) organic stenosis with tumor; and (2) functional stenosis. Organic stenosis is of congenital origin. In the fetus the pylorus is large and forms a very great part of the stomach, greater than it does in infancy. If one looks at the picture of the pylorus of the fetus, one is reminded of pyloric tumors. The only way to settle this question is to find these cases in dead-born children, to find instances of pyloric tumors. We should examine the dead-born children more carefully if we wish to solve this problem. Some patients die within one or two weeks, although the operation was successful. I think that this is due to overfeeding, to alimentary intoxication. If a gastro-enterostomy is performed and a large amount of milk is fed into the intestines, alimentary intoxication results, with fever and death.

Dr. Max Einhorn: I have had four cases of congenital stenosis of the pylorus in infants, and success was attained in two of them by stretching the pylorus. This method deserves to be used more. The stretching was performed in all four of my cases. In two patients there was a real stenosis and not a spasm and successful results followed this stretching of the pylorus. In two of the cases the results were just as good as could have been obtained by surgical measures. After the stretching the stomach began to be emptied and the children began to improve. These were cases of pyloric obstruction. In two cases I succeeded in stretching the pylorus, but the patients died. There was no stenosis but rather a spasm. Stretching was done in these two cases, but without the desired results.

Dr. William A. Downes: No surgeon, whether urged by a pediatrician or other medical adviser, would attempt to operate in pyloric stenosis in infants on the basis of tumor and peristaltic wave alone. Data from every point of view should be had before resorting to operative interference.

ASSOCIATION OF AMERICAN PHYSICIANS

Twenty-Ninth Annual Meeting, held at Atlantic City, N. J., May 12 and 13, 1914

(Concluded from page 1838)

The Inspiratory Exaggeration of the Dicrotic Wave in Pericarditis

Dr. Albert E. Taussig, St. Louis: Ordinarily, the dicrotic wave in the radial sphygmogram does not vary in size with the phase of respiration. In pericarditis, however, it becomes more or less exaggerated, sometimes greatly so, during inspiration. In all of five cases studied from this point of view, the phenomenon was observed. Anatomic considerations render its occurrence readily explicable. It may have diagnostic significance.

The Influence of Benzol Inhalations on Experimental Pulmonary Tuberculosis in Rabbits

Dr. William Charles White, Pittsburgh, Pa: Benzol benzene, is the best solvent for the fat portion of the tubercle bacillus. It extracts a greater percentage of fat than any other single solvent will take from the bacillary substance. Because benzol can easily be vaporized and utilized as an anesthetic, it was thought possible in this way to dissolve the living tubercle bacillus after its entrance into the pulmonary capillary system by way of the ear-vein and before the formation of the tubercle. It was hoped in this way to obtain a solution of all the living portions of the tubercle bacillus within the body and the possible development of a retardation of the process produced by a fatal dose of tubercle bacilli and the establishment of an immunity to a further dose of the organism. Contrary to the desire expressed in the theory, I found that in every instance whether the infecting tubercle bacilli were of low virulence or of high virulence, the resulting infection in rabbits was very much more severe in those treated by inhalation of benzol than in those infected with the same weight of infecting organism.

The symptoms produced in rabbits by the inhalation of benzol were similar to those described by Sollmann for the inhalation of gasoline vapors. Animals may be given benzol inhalations, 5 c.c. every second day for periods up to three and even four weeks, without resulting in death. The resulting leukopenia varies very much. The lowest white-cell count was 3,800 per cubic millimeter. The red-cell anemia is very variable, the lowest in our series being 3,600,000 per cubic millimeter. The majority retained a normal red-cell count. The blood-smears and blood-counts exhibited changes similar to those described for the injections of benzol by Selling and others.

In all, thirty-three animals were used, twelve controls and twenty-one treated. The pathologic findings in many of these animals were very striking. In 30 per cent. of the treated animals, after receiving 5 c.c. inhalations of benzol every second day for three weeks, and then being allowed to live two or three weeks longer, extreme enlargement of the spleen was found. In one instance the spleen measured 13 by 3.5 by 3 cm., and the circumference of its largest part was 9.5 cm. There was a large hemorrhage in the substance of this spleen. In all twenty-one treated animals there was only a single case of purpura with hemorrhages into the mucous membrane of the stomach and bowel. There were marked fatty changes both in the liver and in the kidneys of the treated animals.

Some Relations of the Brain and of the Olfactory Apparatus to the Processes of Immunity

Dr. Henry Sewall, Denver: Guinea-pigs sensitized to horse-serum may be desensitized by residence in a horse-stable. It is probable that this reaction may be rapidly achieved through the olfactory sense or more slowly by absorption through the respiratory membrane. The period of antianaphylaxis is of less than two days' duration. The converse of this, sensitization of normal guinea-pigs in stable-air, I have not been able to achieve. Removal of part of the brain of a sensitized guinea-pig produces much more severe shock than the same amount of injury in a normal animal. This shock is apt to be followed by a period of antianaphylaxis of short duration. Section of the olfactory nerves within the cranial cavity preceding the brain operation by a day or more abolishes the tendency to shock. Such nerve section in the normal animal also seems to reduce the shock arising from definite brain injury. [Depression of the olfactory sense through cocain and the resemblance of symptoms from poisoning with this drug to those of anaphylaxis are discussed]. The body as a whole may be sensitized through the peripheral application of horse-serum after a definite latent period which does not seem to be affected by previous general sensitization.

The Normal Amount of Diastatic Ferment in the Urine and Feces and Its Variation in Diseases of the Pancreas

Dr. Thomas R. Brown, Baltimore: In healthy persons the diastase-content of the urine falls within quite definite limits. Markedly small amounts of this ferment in the urine, in the absence of renal changes, are suggestive, although not diagnostic, of pancreatic disease. The stool, if a rigorously exact method is carried out as to food (milk), purgative employed, preservation of specimen, estimation of ferment, etc., also furnishes a content within definite limits. Extensive carcinoma of the pancreas showed no diastase in the tube of least dilution in the method which I used, and this absence of ferment should prove of great help in the diagnosis of this condition. In chronic pancreatitis, diastase is present in the stool, but in markedly diminished amounts. In achylia gastrica the diastase-content of the stool was practically normal in all the cases examined.

Aconite as a Vasodilator

Dr. William Hanna Thomson, New York: I regard aconite as the most efficacious vasodilator in chronic interstitial nephritis when given systematically in full doses. It at once reduces the blood-pressure, produces a full and compressible pulse, and greatly increases the percentage of the elimination of urea in interstitial nephritis. The most important action of aconite, when administered in interstitial nephritis, is to increase the elimination of urea. The beneficial effects of aconite are particularly pronounced in mental derangements of the nature of melancholia with high blood-pressure.

The Subcutaneous Administration of Oxygen as a Therapeutic Measure

Dr. John McCrae, Philadelphia: For the last two or three months I have used oxygen in this way, which I believe is the rational method of administering it and I believe that properly placed, it is useful. I employed it in a surgical case after a severe operation. The patient looked as though he might die in a short time. His respiration was 60; he had extreme edema of the lungs, extreme pallor, profuse perspiration, and signs of impending death. With repeated injections of oxygen the man recovered. I have used oxygen in thirty cases and believe it should be a part of the armamentarium of the surgical operating-room.

1. **Medical Diagnosis in Relation to Surgery.**—The value of a medical examination, not only in obscure but also in plain, simple surgical cases is emphasized by Riesman. He says that the physician might find diabetes, nephritis, grave anemia, bronchitis, or serious heart disease, any one of which would influence the surgeon in his work. Many delayed deaths after operation might thus be averted. He also feels that in medical cases which may at any time assume a surgical aspect, the surgeon should be consulted long before an operation becomes imperative. In order to increase his diagnostic skill, the physician should make it a rule to be present at all operations on cases that have come before him.

2. **Uterine Growths and Exophthalmic Goiter.**—Elsner calls attention to the large proportion of uterine growths associated with goiter, typical and atypical exophthalmic goiter, and mentions the frequency of the atypical cases, to encourage the thorough examination of all the organs of the body in the presence of goiter, large or small. He says that if this be done, the number of associated anomalies will prove surprising.

3. **Disease of Nerves of Cauda Equina.**—The histories of the five patients seen by Kennedy and Elsberg are almost exactly alike in the nature and sequence of incident. In the third and fourth patients the symptoms were progressive in each for about two years, in the second for about one year, and in the first for but six months. Pain was present in all from the beginning; it was sharp, shooting, and burning in character, and was felt almost entirely in the backs of the thighs and in the calves. By the last patient it was described also as needling and cramp-like. In the first four patients the pain was, at the beginning, strictly unilateral, being felt in both legs after the lapse of some weeks or months. The leg first involved remained throughout the illness more affected than its fellow. All but the third patient complained much of tingling and numbness, involving sometimes the feet, sometimes the knees, and in the last two patients the entire surface of the lower extremities. Atrophy of the anterior tibial muscles, with loss of the power of dorsiflexion at the ankle, was a prominent feature in four of the series; in the exception there was a spasticity of the lower extremities, which was more marked on the right than on the left side.

The objective sensory changes showed an astonishing uniformity; in all, the main incidence of the disease had fallen on the lowest roots of the cauda, the sacral roots were always affected, and with the utmost severity. In one patient all the lumbar roots were also involved though to a somewhat lesser degree than were their more lowly placed fellows. In three only had the lowest lumbar roots become diseased to such an extent as to abolish or depress function. The more markedly the lower sacral roots were involved the more complete was the sphincter disturbance. The disorganization of the functions of the bladder and rectum was complete in all but the third case, in which precipitancy and frequency of micturition prevailed. The first third and last cases showed that disease had produced destructive changes in the cord itself; in them the plantar reflex was of the pathologic-extensor type. The abdominal reflexes were present in all the patients. In but one were the ankle-jerks obtained in the affected limbs. The knee-jerks became lost, as in the last case, coincident with the upward progress of the disease.

None of the patients gave either a history or indication of luetic infection. In all, the Wassermann test was carried out in both the blood and cerebrospinal fluid, with completely negative results in every instance. In only one case did the cerebrospinal fluid give any indication of the presence of a disease condition within the dura and in it was of doubtful interpretation, showing a negative Wassermann test and an increased amount of globulin, with twenty lymphocytes per cubic centimeter, a cytologic count, insufficient to accompany any tuberculous process.

The conditions found at operation were the following: In two patients a large number of the caudal roots and in the other three all the roots were swollen, congested, and of a bluish-red color. The changes seemed to be due to an intense hyperemia on the surface of the nerves, and extended into the nerves themselves. Adhesions between the nerve-roots were present in only one case; in the others the only changes were swelling and discoloration. In all five patients the inner surface of the dura was smooth and glistening, and without signs of inflammatory change though in two of them a few small areas of hyperemia were observed. The axis-cylinders showed various degrees of swelling, loss of normal staining reaction, some of them showing granular degeneration, fragmentation and absorption.

8. **Indirect Transfusion of Blood.**—The method described by Moss consists of two parts: 1. Obtaining blood from the donor, by means of an aspirating apparatus, and its defibrination by shaking in flasks with glass beads. 2. The introduction, intravenously of the defibrinated blood into the patient. The method is described in detail.

9. **Rôle of Carotid Arteries**—Hunt urges that in all cases presenting cerebral symptoms of vascular origin, the main

arteries of the neck be carefully examined for a possible diminution or absence of pulsation. In the large majority of cases, a sudden obstruction may occur without softening producing nothing more than mild and transient cerebral symptoms. On the other hand, this may so cripple the cerebral circulation in advanced life that functional deficiencies result and the one hemisphere may be more predisposed to softening processes than the other. Hunt emphasizes the occurrence of diminished pulsation of the carotid on the side of the softening as an occasional symptom in cases of thrombotic hemiplegia, and suggests that the impairment of circulation through the carotid so interferes with the general circulation of the hemisphere as to predispose to thrombus formation and encephalomalacia. He also particularly emphasizes the occurrence of unilateral vascular changes, pallor or atrophy of the disk with contralateral hemiplegia in obstruction of the carotid artery. Unilateral headaches and vertigo, especially in assuming the upright posture, epileptiform attacks, failing memory, attacks of threatened hemiplegia, cerebral intermittent claudication, are some of the vascular symptoms which should suggest the possibility of carotid obstruction.

10. **Wolff-Junghans' Test for Gastric Cancer.**—When carefully performed and interpreted Smithies says the Wolff-Junghans' test for demonstration of dissolved albumin in gastric extracts was positive or suspicious in 80 per cent. of his series of gastric cancer. In this series it was a more constant finding in gastric extracts than were absent free hydrochloric acid, the presence of lactic acid, and the glycytryptophan test. It was rather more constant than tests for occult blood and the demonstration of gastric motor inefficiency. It was not so consistent in its manifestation as the demonstration of organisms of the Boas-Oppler group or the increase in the formol index. In extragastric malignancy, gastric syphilis and nephritis the Wolff-Junghans' test is inconstant. In the differentiation between malignant and non-malignant achylias the Wolff-Junghans' test, when interpreted in connection with other clinical and laboratory data, is of considerable value. Positive reactions are rarely obtained in the achylias of primary anemia, simple achylia gastrica, and simple achlorhydrias when such are unassociated with gastric motor inefficiency. Simple gastric and duodenal ulcers, especially when accompanied by pyloric stenosis or gastric atony, may give confusing resources to the Wolff-Junghans' test. The presence of blood in gastric extracts may be a factor in the production of certain atypical positive tests.

11. **Jaundice in Tuberculosis.**—Cruice has seen 7 cases of jaundice among 1,748 cases of chronic pulmonary tuberculosis. He believes that jaundice occurring in the course of chronic tuberculosis is probably due to some form of tuberculosis of the liver, either extrahepatic or intrahepatic. The grade of the jaundice is helpful in surmising the pathologic condition, intense jaundice being probably due either to pressure of tuberculous glands on the extrahepatic ducts or to some form of the solitary tubercles of the liver; milder forms being produced by a miliary tuberculosis of the liver.

12. **Degeneration of Islands of Langerhans.**—Six cases of hyaline degeneration of the islands of Langerhans in which there was no evidence of diabetes occurred in subjects aged over 37 years. In addition to the hyaline changes there were found in every case more or less sclerosis of the insular capillaries, and a chronic interacinar pancreatitis of the type usually encountered in diabetes mellitus. The explanation of this phenomenon, which has seemed most likely to Cecil is that hyaline degeneration of the islands, may occur up to a certain point without producing diabetes. When a number of islands sufficient to interfere with carbohydrate metabolism have been involved, diabetes ensues. The hyaline changes in the island of Langerhans, Cecil says, have been associated in every case with hyaline degeneration of the renal glomeruli. The lesions in both instances are possibly referable to sclerosis of the smaller vessels supplying these structures.

24. **Relationship of Anaphylaxis to Immunity.**—For the last two years Gurd, in association with Dr. J. C. Meakins, has carried out experiments in the hope of proving by direct methods the presence in the serum of so-called immune animals, of a substance capable of protecting the sensitized animal against the manifestations of anaphylaxis. He found that the blood-serum of immune animals contains not only sensitizing bodies, but also some substance which is potent to protect the animal from the effects of the cleavage toxic split products. For purposes of explanation Gurd calls the anaphylactic ferment the lysin of the first order. This is the cause of the anaphylactic state. The ferment capable of digesting the toxic split product he has designated the lysin of the second order. It is to the presence in the tissues of lysins of the second order that the repeatedly inoculated animal owes its so-called immunity to the toxin.

With reference to the second order of lysin, Gurd found that with whole proteins used as injection material the lysins of the first order are always produced first. The lysins of the first order are elaborated to a much more marked extent than are those of the second order; all immune animals are therefore potentially sensitized. This is shown by allergic reactions and passive anaphylaxis as well as by direct experiments, such as those reported in this paper. The persistence of the lysins of the second order in the tissues is much shorter than that of the first order. "Immune" animals, therefore, become ultimately markedly sensitive.

1. **Medical Diagnosis in Relation to Surgery.**—The value of a medical examination, not only in obscure but also in plain, simple surgical cases is emphasized by Riesman. He says that the physician might find diabetes, nephritis, grave anemia, bronchitis, or serious heart disease, any one of which would influence the surgeon in his work. Many delayed deaths after operation might thus be averted. He also feels that in medical cases which may at any time assume a surgical aspect, the surgeon should be consulted long before an operation becomes imperative. In order to increase his diagnostic skill, the physician should make it a rule to be present at all operations on cases that have come before him.

2. **Uterine Growths and Exophthalmic Goiter.**—Elsner calls attention to the large proportion of uterine growths associated with goiter, typical and atypical exophthalmic goiter, and mentions the frequency of the atypical cases, to encourage the thorough examination of all the organs of the body in the presence of goiter, large or small. He says that if this be done, the number of associated anomalies will prove surprising.

3. **Disease of Nerves of Cauda Equina.**—The histories of the five patients seen by Kennedy and Elsberg are almost exactly alike in the nature and sequence of incident. In the third and fourth patients the symptoms were progressive in each for about two years, in the second for about one year, and in the first for but six months. Pain was present in all from the beginning; it was sharp, shooting, and burning in character, and was felt almost entirely in the backs of the thighs and in the calves. By the last patient it was described also as needling and cramp-like. In the first four patients the pain was, at the beginning, strictly unilateral, being felt in both legs after the lapse of some weeks or months. The leg first involved remained throughout the illness more affected than its fellow. All but the third patient complained much of tingling and numbness, involving sometimes the feet, sometimes the knees, and in the last two patients the entire surface of the lower extremities. Atrophy of the anterior tibial muscles, with loss of the power of dorsiflexion at the ankle, was a prominent feature in four of the series; in the exception there was a spasticity of the lower extremities, which was more marked on the right than on the left side.

The objective sensory changes showed an astonishing uniformity; in all, the main incidence of the disease had fallen on the lowest roots of the cauda, the sacral roots were always affected, and with the utmost severity. In one patient all the lumbar roots were also involved though to a somewhat lesser degree than were their more lowly placed fellows. In three only had the lowest lumbar roots become diseased to such an extent as to abolish or depress function. The more markedly the lower sacral roots were involved the more complete was the sphincter disturbance. The disorganization of the functions of the bladder and rectum was complete in all but the third case, in which precipitancy and frequency of micturition prevailed. The first third and last cases showed that disease had produced destructive changes in the cord itself; in them the plantar reflex was of the pathologic-extensor type. The abdominal reflexes were present in all the patients. In but one were the ankle-jerks obtained in the affected limbs. The knee-jerks became lost, as in the last case, coincident with the upward progress of the disease.

None of the patients gave either a history or indication of luetic infection. In all, the Wassermann test was carried out in both the blood and cerebrospinal fluid, with completely negative results in every instance. In only one case did the cerebrospinal fluid give any indication of the presence of a disease condition within the dura and in it was of doubtful interpretation, showing a negative Wassermann test and an increased amount of globulin, with twenty lymphocytes per cubic centimeter, a cytologic count, insufficient to accompany any tuberculous process.

The conditions found at operation were the following: In two patients a large number of the caudal roots and in the other three all the roots were swollen, congested, and of a bluish-red color. The changes seemed to be due to an intense hyperemia on the surface of the nerves, and extended into the nerves themselves. Adhesions between the nerve-roots were present in only one case; in the others the only changes were swelling and discoloration. In all five patients the inner surface of the dura was smooth and glistening, and without signs of inflammatory change though in two of them a few small areas of hyperemia were observed. The axis-cylinders showed various degrees of swelling, loss of normal staining reaction, some of them showing granular degeneration, fragmentation and absorption.

8. **Indirect Transfusion of Blood.**—The method described by Moss consists of two parts: 1. Obtaining blood from the donor, by means of an aspirating apparatus, and its defibrination by shaking in flasks with glass beads. 2. The introduction, intravenously of the defibrinated blood into the patient. The method is described in detail.

9. **Rôle of Carotid Arteries**—Hunt urges that in all cases presenting cerebral symptoms of vascular origin, the main

found by Thalhimer and Rothschild in three cases of chorea without joint manifestations, proving the close relation of this condition to rheumatism. They were absent in fourteen cases of subacute bacterial endocarditis due to *Streptococcus mitis.* They were not found in infections of the endocardium with the gonococcus, staphylococcus, streptococcus or pneumococcus. Even in the absence of a rheumatic history the authors agree with Fraenkel, that the presence of Aschoff bodies signifies a previous rheumatic infection. Aschoff bodies are not always found in rheumatic carditis, where the infection antedates death by a long period, but the healed remains, represented by sclerotic patches (*"Schwielsen"*), are present. Thalhimer and Rothschild suggest that the cases of arthritis characterized by the presence of the submiliary nodules of Aschoff in the myocardium be placed in one group and called for the time being "rheumatism"; and the cases with articular manifestations, yielding positive bacteriologic findings and no Aschoff bodies, should be classified according to the infecting microorganisms concerned, and not as rheumatism.

57. **Experimental Focalized Myocardial Lesions.**—By the intravenous injection into 42 rabbits of *Streptococcus mitis.* Thalhimer and Rothschild produced focalized myocardial lesions which are identical with those caused by the injection of *Streptococcus rheumaticus,* and with those produced by Bracht and Wächter with *Streptococcus viridans.* The lesions differ from those produced by injections of streptococci from the Chicago epidemic of sore throat (epidemic streptococcus). They are not identical with Aschoff bodies and are easily differentiated from them. They also differ from the foci produced by Jackson and Coombs, who describe their lesions as being either Aschoff bodies or similar formations. The myocardial lesions of the rabbit appear to be caused by toxins liberated by the streptococci injected and not by the living organisms themselves. The only point of similarity between the experimental lesions and those found in cases of rheumatic carditis in man is their focalized nature.

58. **Experimental Arthritis in Rabbit.**—Rothschild and Thalhimer produced arthritis in 50 per cent. of the rabbits injected with *Streptococcus mitis.* The character of the arthritis is identical with that produced by *Micrococcus rheumaticus.* The exudate in and about the joints partakes of the same nature as that caused by *Streptococcus rheumaticus.* Bacteriologic studies show that *Streptococcus mitis* can be recovered from about one-third of the affected joints. Arthritis produced by other types of streptococci differs by reason of greater destruction of tissue, by being more permanent in character, and by the exudate containing large numbers of polymorphonuclear leukocytes. The deduction of a distinct variety or species of streptococcus based on the power to cause arthritis in rabbits, the authors claim, is unwarranted.

59. **Migration of Adult Tertian Malarial Parasite.**—What appear to be certain definite stages in the migration of the malarial parasite from red corpuscle to red corpuscle were demonstrated by Rowley-Lawson thus giving a reasonable explanation of the loss of red corpuscles which cannot be accounted for by the destruction of the infected corpuscles at the time the parasites segment. Migration to other red corpuscles is a satisfactory explanation of the ultimate fate of the young parasites seen in instances of multiple infection of single corpuscles.

60. **Nature of Serum Antitrypsin.**—The ferment inhibiting action of the serum believed by Jobling and Petersen to be due to the presence of compounds of the unsaturated fatty acids. These fatty acid compounds may be removed from the serum by means of chloroform or ether. Soaps prepared by saponifying the chloroform or ether extracts inhibit the action of trypsin. The anti-enzyme action of the serum can be removed by filtering acid serum through kaolin, and can in part be restored by extracting the kaolin. The decrease in strength of anti-enzyme in old sera is probably due to the action of the serum lipase. Iodin, potassium iodid or hydrogen peroxid remove the inhibiting action of the serum. Soaps of the unsaturated fatty acids lose their ferment inhibiting action when heated with serum at 70 C.

61. **Serotoxin.**—Jobling and Petersen found that sera from which the protective lipoids (unsaturated fatty acids) have been removed are toxic for the homologous animal. The toxicity is due to three factors: (a) an alteration in the mechanism of coagulation, with resulting intravascular coagulation; (b) the exposure of the native serum proteins; (c) the formation of toxic split products (primary proteoses) by autolysis. A definite maximum of toxicity can be determined, with a final stage of atoxicity due to continued autolysis. Hirudin and sodium citrate do not protect animals. Heating to 70 C. destroys, or greatly lessens the toxicity of the serotoxin, although the isolated proteoses are toxic after boiling. The return of the extracted lipoids (saponified) neutralizes the toxicity. Unsaturated soaps also neutralize the toxicity. Sublethal doses produce extreme prostration, marked fall in body temperature, no eosinophilia, and an increase of antitrypsin. Sublethal doses of rapidly prepared chloroform sera cause a decrease in coagulation time; sublethal doses of autolyzed sera cause an increase in coagulation time. Previously injected animals are more resistant (increased antiferments). Iodized animals are less resistant (decreased antiferments).

63. **Factors of Resistance to Heteroplastic Tissue Grafting.**—It has been shown that the chick embryo offers suitable conditions for the growth of implanted tissues whether these be embryonic or adult of the same species or of a foreign one. The chick at about the time of hatching develops a defensive mechanism against the tissue of foreign species. This resistance, Murphy says, can be supplied to the embryo in the early stages if grafts of adult spleen or bone-marrow are implanted. Under these conditions the embryo exhibits the same resistance to foreign tissue as does the adult, and presents the same histologic manifestations about the graft. Furthermore, the same tissues, spleen and bone-marrow, when grafted into an embryo with an established and growing rat tumor, bring about a retrogression and absorption of the foreign tissue. Other adult tissues do not supply this power to embryo.

fever cases without asthma were negative for both tests. Five cases of bronchial asthma and five cases of hay-fever, without sensitiveness to horses, gave negative results.

Goodale is convinced that in horse asthma, an anaphylactic reaction may occur after the administration of horse-serum; in horse fever with nasal symptoms alone, this danger is less or not at all to be feared, and in other types of asthma and of vasomotor rhinitis it is not present.

39. **Formation of Glycocoll.**—The data obtained in experiments by Epstein and Bookman show that alanin, free or combined with a benzoyl radical, fails to yield glycocoll. This result is in accord with work of Magnus-Levy. From the structural character of alanin it is not conceivable that it can be directly converted into glycocoll. The authors' results serve to show, however, that in its decomposition in the body, alanin does not yield cleavage products which can be synthesized into glycocoll. Furthermore, alanin has no direct or indirect effect on hippuric acid metabolism. The increased output of hippuric acid, and hence glycocoll, observed after the administration of benzoyl-leucin the authors suggest is probably not a function of the benzoyl radical of the compound.

46. **Synthesis of Hippuric Acid in Organism.**—In rabbits fed on a glycocoll free diet of milk, Lewis found that the ingestion of sodium benzoate causes no marked rise in the elimination of total nitrogen. The nitrogen eliminated as hippuric acid appears to be derived at the expense of the nitrogen normally present in the urine as urea, since the urea elimination decreases with increased hippuric-acid elimination. The synthesis of glycocoll for the purposes of detoxication of the benzoate results from a deviation of the normal path of catabolism and not from a specialized metabolism. These results are in agreement with those obtained by McCollum and Hoagland in their studies on pigs reduced to their endogenous protein metabolism.

48. **Emotional Glycosuria.**—In order to obtain additional data on the subject of glycosuria in the insane, the authors examined the urine of 192 patients at the McLean Hospital for the Insane. In 22 of these they found unmistakably positive sugar reactions with Nylander's, Benedict's and the phenylhydrazin tests. The great majority, but not all of those who had sugar in the urine, suffered from depression, apprehension or excitement. Some of them had been in apparently the same condition with reference to the emotional state for several years. Of 664 consecutive urine examinations made at the Danvers State Hospital for the Insane, the number giving a positive test for sugar was 58. Of 34 second-year medical students examined before and after an examination one had sugar both before and after the examination. Of the remaining 33, 6, or 18 per cent., had small but unmistakable traces of sugar in the urine passed immediately after the examination.

A similar study was made on second-year women students. Since these students were younger and presumably much more excitable than the medical students it was thought that even more striking results might be obtained. This expectation did not prove well founded. Out of 36 taking the examination and who had no sugar in the urine on the day before, 6 of the 17 per cent. eliminated sugar with the urine passed immediately after the examination. It seems reasonably certain from the results obtained that pronounced mental and emotional strain may produce temporary glycosuria in man.

49. **Glycollic Aldehyd in Phlorizinized Dogs.**—Glycollic aldehyd has been prepared from the crystallin dihydroxyfumaric anhydrid of Fenton and Jackson. Given to fully phlorizinized dogs in single doses of about 5 per cent. strength subcutaneously it has apparently caused an increased breakdown of protein as evidenced by a rise in the urinary nitrogen and a corresponding increase of the sugar while G : N remained constant. The initial rise has been followed in later periods by a fall in all the urinary components examined. When given very slowly in dilute 1 per cent. solution there has been observed an absolute rise in the glucose excretion out of proportion to the rise in the nitrogen, hence an increased G : N ratio not due merely to a lessened nitrogen output but suggestive of a new formation of glucose out of glycollic aldehyd itself. Some 45 to 75 per cent. of the glycollic aldehyd given appears to have escaped oxidation and become converted into glucose in these latter experiments. Judgment is reserved as to whether the small increases of reducing substances seen in these experiments are due to a conversion of glycollic aldehyd into d-glucose or to some other process.

56. **Nodules of Aschoff in Rheumatic Fever.**—In rheumatic myocarditis, foci, termed submiliary nodules of Aschoff, are present which are characteristic of the rheumatic infection. They are most frequently found in the walls of the left ventricle, the auricles usually escaping. The nodules were

found by Thalhimer and Rothschild in three cases of chorea without joint manifestations, proving the close relation of this condition to rheumatism. They were absent in fourteen cases of subacute bacterial endocarditis due to *Streptococcus mitis.* They were not found in infections of the endocardium with the gonococcus, staphylococcus, streptococcus or pneumococcus. Even in the absence of a rheumatic history the authors agree with Fraenkel, that the presence of Aschoff bodies signifies a previous rheumatic infection. Aschoff bodies are not always found in rheumatic carditis, where the infection antedates death by a long period, but the healed remains, represented by sclerotic patches (*"Schwielsen"*), are present. Thalhimer and Rothschild suggest that the cases of arthritis characterized by the presence of the submiliary nodules of Aschoff in the myocardium be placed in one group and called for the time being "rheumatism"; and the cases with articular manifestations, yielding positive bacteriologic findings and no Aschoff bodies, should be classified according to the infecting microorganisms concerned, and not as rheumatism.

57. **Experimental Focalized Myocardial Lesions.**—By the intravenous injection into 42 rabbits of *Streptococcus mitis.* Thalhimer and Rothschild produced focalized myocardial lesions which are identical with those caused by the injection of *Streptococcus rheumaticus,* and with those produced by Bracht and Wächter with *Streptococcus viridans.* The lesions differ from those produced by injections of streptococci from the Chicago epidemic of sore throat (epidemic streptococcus). They are not identical with Aschoff bodies and are easily differentiated from them. They also differ from the foci produced by Jackson and Coombs, who describe their lesions as being either Aschoff bodies or similar formations. The myocardial lesions of the rabbit appear to be caused by toxins liberated by the streptococci injected and not by the living organisms themselves. The only point of similarity between the experimental lesions and those found in cases of rheumatic carditis in man is their focalized nature.

58. **Experimental Arthritis in Rabbit.**—Rothschild and Thalhimer produced arthritis in 50 per cent. of the rabbits injected with *Streptococcus mitis.* The character of the arthritis is identical with that produced by *Micrococcus rheumaticus.* The exudate in and about the joints partakes of the same nature as that caused by *Streptococcus rheumaticus.* Bacteriologic studies show that *Streptococcus mitis* can be recovered from about one-third of the affected joints. Arthritis produced by other types of streptococci differs by reason of greater destruction of tissue, by being more permanent in character, and by the exudate containing large numbers of polymorphonuclear leukocytes. The deduction of a distinct variety or species of streptococcus based on the power to cause arthritis in rabbits, the authors claim, is unwarranted.

59. **Migration of Adult Tertian Malarial Parasite.**—What appear to be certain definite stages in the migration of the malarial parasite from red corpuscle to red corpuscle were demonstrated by Rowley-Lawson thus giving a reasonable explanation of the loss of red corpuscles which cannot be accounted for by the destruction of the infected corpuscles at the time the parasites segment. Migration to other red corpuscles is a satisfactory explanation of the ultimate fate of the young parasites seen in instances of multiple infection of single corpuscles.

60. **Nature of Serum Antitrypsin.**—The ferment inhibiting action of the serum believed by Jobling and Petersen to be due to the presence of compounds of the unsaturated fatty acids. These fatty acid compounds may be removed from the serum by means of chloroform or ether. Soaps prepared by saponifying the chloroform or ether extracts inhibit the action of trypsin. The anti-enzyme action of the serum can be removed by filtering acid serum through kaolin, and can in part be restored by extracting the kaolin. The decrease in strength of anti-enzyme in old sera is probably due to the action of the serum lipase. Iodin, potassium iodid or hydrogen peroxid remove the inhibiting action of the serum. Soaps of the unsaturated fatty acids lose their ferment inhibiting action when heated with serum at 70 C.

61. **Serotoxin.**—Jobling and Petersen found that sera from which the protective lipoids (unsaturated fatty acids) have been removed are toxic for the homologous animal. The toxicity is due to three factors: (a) an alteration in the mechanism of coagulation, with resulting intravascular coagulation; (b) the exposure of the native serum proteins; (c) the formation of toxic split products (primary proteoses) by autolysis. A definite maximum of toxicity can be determined, with a final stage of atoxicity due to continued autolysis. Hirudin and sodium citrate do not protect animals. 92. **Inlay Bone Graft in Fresh Fractures.**—The graft used by Albee is removed from the fractured bone, instead of from the crest of the tibia, by making the segment removed from one fragment double the length of that removed from the other, if possible 5½ inches for the long fragment and 2½ inches for the length of the short fragment.

After stripping up the periosteum overlying the area from which the short segment is to be removed—and this stripping should be done with a sharp instrument to insure the removal of the underlying osteogenetic cells—the gutter is started by the twin saws adjusted at a suitable distance apart, depending on the size of the graft and gutter to be formed. The long segment to be removed from the other fragment is outlined with the twin saws, adjusted at the same distance as when outlining the short segment, but the periosteum is removed from only the distal half of the long segment. These parallel saw cuts are now continued through the bone to the medullary cavity, with the single saw held at such an angle as to cause the cuts to converge in approaching the medullary cavity, in order to prevent the graft, when forced tightly into position, from dropping into the medullary cavity beneath. To free the ends of the grafts transverse cuts are made, either with a smaller motor saw or with a chisel.

The breadth of the saw-blade cuts is sufficient to allow the graft, when turned about and placed in position, to sink slightly below the borders of the gutter, thus furnishing a margin along the sides of the long graft into which dowel holes are drilled obliquely outward to receive the autogenous dowel pegs made by splitting the removed short segment into fragments and running them through the doweling instrument. When these pegs are driven into place, the graft is held securely, and proper alignment of the fragments is insured by the leverage action of the accurately fitting graft to its gutter bed. The periosteum is then drawn over the denuded portion of the graft and held by a few catgut sutures; also the periosteum left at the site of the short fragment is drawn across the gap and sutured with catgut.

107. **Eventration of Diaphragm.**—In Stein's case examination revealed a typical eventration of the diaphragm with the stomach, the greater part of the small and large intestine, the spleen, the left lobe of the liver, the tail of the pancreas, and the upper pole of the left kidney in the chest. The heart was found greatly enlarged and pushed extremely to the right. The lungs were found above and to the right of the diaphragm, all compressed except the lower lobe of the right lung. The diaphragm on the left side was found to be a fibrous dome, thin and gray in appearance, extending to the level of the second interspace, in which no muscle fibers were seen. The remaining abnormality was that of undescended testes, which were found in the abdomen.

111. **Experimental Work in Bone Transplantation.**—The following conclusions based on experiments are submitted by Lewis: 1. That cortical bone, free of its periosteum, endosteum, and marrow will retain its vitality and proliferative powers when subdivided into small fragments and replaced in the tissues. Also that contact with living bone is unnecessary for the growth of these transplants. 2. That larger pieces of bone may be transplanted and remain alive—not being merely grown into by the bone in which they come in contact. 3. That bones may unite after fracture or a space fill in after resection without the aid of any periosteal or bony bridge, and that transplanted fascia may be made to take up the nutritional and limiting functions of the periosteum.

Lewis reports an observation of a case in which a portion of bony shaft 3 centimeters in length was removed and the adjacent periosteum of the ends of the shaft thoroughly scraped away. The interval between the ends was then surrounded by a transplant of fascia which was made to extend up and down along the shaft for some distance. At the post mortem nine weeks later complete bony filling in of the space with excessive callus formation had occurred. The fascia transplant had fused above and below with the periosteum and could not be differentiated from it. In another experiment the same method was followed except that no fascia transplant was used, the space between the periosteum and could not be differentiated from it. In this case no periosteal or bony bridge was allowed to remain, in spite of which fact, at post mortem nine weeks later, a good bony filling in of the space was found to have occurred.

116. Abstracted in THE JOURNAL, Dec. 6, 1913, p. 2099.

117. Abstracted in THE JOURNAL, Jan. 31, p. 405.

119. **Exposing Pelvic Portion of Ureter.**—With the patient in the Trendelenburg position Birnie makes a median incision beginning close to the pubic bone and extending upward, exposing the space of Retzius in the usual manner. No muscle fibers are cut but the recti are retracted to either side. The point where the parietal peritoneum is reflected onto the bladder is noted and care taken not to open the peritoneal cavity. Starting at the bladder, the peritoneum is wiped away toward the median line separating it from the bladder and pelvic wall, thus exposing the ureter. With retraction one gets a complete exposure of the ureter and any necessary procedures may be carried out under the guidance of the eye. Drainage, if necessary may be instituted through the original incision or through a separate stab wound.

121. **Method of Sterilizing and Storing Catgut.**—The process is divided by Bartlett into three definite steps: drying, sterilization and storage. The ordinary commercial 10-foot catgut strand is divided into four equal lengths, each of which is made into a coil about the diameter of a silver quarter. By twisting the last free end three or four times around the components of this little coil the latter is enabled to maintain its shape. These coils are then strung like beads on a thread so that any desired number can be conveniently handled by simply grasping the thread. The string of catgut coils is dried in a bacteriologist's dry sterilizer for four successive hours at a temperature of 80 F., 90 F., 100 F. and 110 F. centigrade. Let thin gauze be interposed between catgut and metal. This should not be attempted on a damp day or in a room which steam enters. The catgut is immediately placed in liquid albolene (petrolatum liquidum) where it is allowed to remain until "clear" in the sense that the term is used in the preparation of histologic specimens. This is usually accomplished in a few hours, though it has been Bartlett's custom to allow the gut to remain in the oil over night. Thin paper must line the receptacle so that the catgut may not touch its walls.

The vessel containing the oil is placed on a pan of sand and the temperature raised by a gas-flame during one hour to 160 F. centigrade, which temperature is maintained for a second hour. By seizing the thread with a sterile forceps the gut is lifted out of the oil,. an excess of which is allowed to drip off, the thread is cut and the coils dropped into a solution of iodin crystals in Columbian spirits (deodorized methyl alcohol), the proportion of iodin varying according to the diameter of the catgut. For No. 00 it should be 1 to 700; for No. 0, 1 to 600; for No. 1, 1 to 500; for No. 2, 1 to 400; for No. 3, 1 to 300; for No. 4, 1 to 200; the iodin being taken by weight and the alcohol by volume. The material becomes ready for use in a few hours, and should remain in the solution indefinitely without deterioration. A few coils may be removed at any time with no risk of contaminating those left behind.

122. **Operative Procedure for Suppurative Salpingitis.**—Bell's method aims at removing diseased structures as widely as possible, while one ovary, or a portion of it, is preserved, together with sufficient endometrium to ensure the subsequent occurrence of regular menstruation. In other words, both tubes, one ovary and a wedge-shaped portion of the fundus uteri are removed.

4. **Phenomena Attributable to Cerebral Angiospasm.**—The special condition discussed by Russell is spasm constriction of the arterial channels in localized areas of the brain; the term "cerebral angiospasm" is given to the condition. Although the cerebral vessels cannot be seen, the vessels of the retina can be examined by means of the ophthalmoscope, and it has been clearly established that angiospasm occurs in these vessels. Various observers have noted that a temporary loss of vision of one-half of the retina may be associated with marked diminution in the size of the retinal vessels corresponding to the blind field, and that vision returns with the relaxation of the constricted vessels and the reestablishment of the normal blood-supply to the part. From these observations alone Russell believes it is fair to postulate that corresponding constriction can take place in the arteries in localized areas of the brain.

6. **Relation between Epilepsy and Tuberculosis.**—An analysis of 100 deaths among epileptics by Shaw taken seriatim shows that tuberculosis was the cause in 33 cases. A similar analysis of 290 deaths among non-epileptic patients gives the figure 24.1. The tuberculosis mortality is therefore nearly 10 per cent. greater among epileptics. He tried the tuberculin test on 60 epileptics; the resultant reactions were negative in 3 cases, doubtful in 7, and positive in 50. The corresponding figure for 10 non-epileptic patients resident in the epileptic ward was 50.0. A very noticeable peculiarity among epileptics is the marked depression of temperature after even a comparatively small initial rise and the quick response to the tuberculin in the first place. In 7 cases the temperature dropped to 96 F. and below (one reaching 95.4 F.), in 4 cases to 96.2 F., and in 6 to 96.4 F. In 15 cases it dropped to between 96.8 F. and 97.2 F. so that in 31 cases, or over 50 per cent., this sudden depression was marked. In all these cases the epileptic seizures were very severe and frequent, and in the 7 cases in which the temperature fell to 96 F. and below exceptionally so.

The frequency of subnormal temperatures among epileptics was also very marked. Out of the 60 cases under consideration this condition was present in 35; physical signs were present in 22, doubtfully so in 6, and apparently absent in 7 cases. Of all those showing a positive reaction to tuberculin, physical signs were present in 61.6 per cent., and the number of cases in which the right apex was involved as compared with the left is remarkable; out of the total number showing signs of tuberculous deposit (namely, 38), in 33 the right apex was involved. This is a fact of very great interest when it is recollected that it is mainly on the right side that the tracheo-bronchial glands are implicated in children. It is contended by Shaw that epilepsy may be an evidence of tuberculous infection in childhood, probably affecting the bronchial glands, initially, and that the convulsions are due either to reflex irritation so set up or to the resulting toxemia acting on an unstable nervous system, either inherited or acquired. Further, that the constantly recurring seizures not only establish a vicious habit as far as the nervous system is concerned, but also effect tuberculin autoinoculation, thus tending to keep the tuberculous process in check, so that, instead of a fatal termination epilepsy results. Consequently, the advisability of carefully searching for tuberculous foci in children the moment epileptic fits develop, and also the immediate use of tuberculin in their treatment, should receive consideration.

7. Strychnin-Tuberculin Treatment of Tuberculosis.—Whelan gives strychnin injections to all kinds of tuberculous patients, including cases in which tuberculin injections are contraindicated, with the best results. He gives strychnin in acute and chronic cases, in the pyrexial and the apyrexial, in the early stages and in the most advanced, and with invariably good results. It always improves the appetite and general condition. Patients who have a loathing for food soon regain their appetites under its influence. Strychnin, Whelan states, will frequently do away with the painful necessity of adopting gastric lavage and over-alimentation. But the drug must be given by intramuscular or subcutaneous injection, preferably the former. Administered by the mouth it has not the same effects and in large doses will cause tormina and diarrhea, with possibly disastrous results in advanced cases. These effects are never produced by the injections. Hemorrhages from the lungs, Whelan says, are found to be no contra-indication for the strychnin injections. He has given them in such cases with remarkably good effects when the circulation had been quieted by morphin. The following is the solution he invariably uses: ℞ Liquor strychnin hydrochlorid (B.P.) 100 minims; sterile normal saline solution made with camphor water, add to make 400 minims; Signa: 1 in 400 strychnin solution. Dose, 18 to 25 minims.

8. Von Pirquet Cutaneous Tuberculin Reaction.—Leckie holds that the cutaneous reaction is of no prognostic or diagnostic value; that results are more frequently obtained in women and children than in men; that the older the individual the less likely is the reaction to be obtained; old-standing lesions, as distinguished from advanced cases, usually fail; cases of rheumatism give more positive results than tuberculous individuals; late and early reactions have no clinical significance..

13. Development of Heart in Man.—In the first stage of its development the heart according to Waterston is a self-regulating organ. Its rhythmic activity is shown by peristaltic waves of contraction which sweep over it from end to end; at this stage it possesses a continuous muscular coat. It is quite independent of the central nervous system. In the next stage—i.e., when the primitive chambers are being divided—a new mechanism arises in the form of a node of specialized tissue situated at the junction of sinus venosus and atrium, which passes thence to the dorsal wall of the atrium and the region of the pulmonary veins. This is the first of the nodal tissues to appear, and is the precursor of the sinu-atrial node of the adult heart. The a-v bundle and node make their appearance about the time of the further division of the chambers of the heart, as a bundle of fibers lying under the posterior endocardial cushion of the atrial canal, and extending from the atrial wall to the ventricular muscular septum. The evidence goes to show that this bundle is derived from the tissues in which it appears, and that from the first it is surrounded by a sheath of loose connective tissue. Fibers and cells from the central nervous system invade this bundle, and also go to other portions of the heart wall, but the intrinsic regulating mechanism appears to arise independently of the nervous system, and is connected only secondarily through that system with other parts of the body.

16. Subtotal Gastrectomy for Cancer.—Five years ago Moullin did a subtotal gastrectomy on a woman, 51 years of age and rather stout, for gastric cancer. A guarded prognosis was given, chiefly because of the persistence and severity of the pain. An incision was made across the stomach, running from the right side of the esophagus downward and slightly to the left, so as to remove the whole of the stomach except a small portion at the cardiac end. The upper portion of this incision was closed with a double row of sutures; the lower end was sutured to the edges of an incision of corresponding length in the jejunum, so as to form a gastro-jejunostomy. The patient was sick once forty-eight hours after the operation, bringing up some bile, but in other respects recovery was quite uneventful. In the portion of stomach removed there was a characteristic carcinomatous growth originating on the margin of an old chronic ulcer. The patient is alive and well today with no evidence of recurrence.

19. Malignant Tumor of Bones.—In malignant tumors which affect bone, to avoid the resection of the affected portion of bone Wenglowski sterilizes the bone to kill all the elements of the tumor, and then to allow the dead bone to remain in its natural connection with the healthy part of the bone. The sterilization is performed by means of steam under high pressure. For this purpose an ordinary autoclave is used, or even a steam kettle may be employed; in it steam is formed under a pressure of from 3 to 5 atmospheres. On the spout of the kettle Wenglowski puts a thick walled rubber tube from 1½ to 2 meters long, and on the other end of this tube he fastens a piece of metal tubing. This metal piece has many holes for the escape of the steam. For the sterilization of the front side of the bone, he uses a straight metal tube with terminal holes; for the under surface of the bone he uses a larger flattened tube which is slightly curved, and the concave side has the holes for the escape of the steam. After the removal of the tumor in the soft parts he scrapes off the rest of the tumor on the bone and lays bare the bone as for a resection. To protect the soft parts from burning he covers them with three or four thicknesses of gauze; on this he puts a thin sterilized layer of asbestos, and finally a metal plate. This metal plate is used to guard the soft parts from the hot condensation water which might trickle through the gauze and the asbestos. Then the curved metal tube is passed under the bone and the steam is turned on.

To heat the tibia to from 75 to 80 C. it is necessary to apply the steam for three minutes, for the lower jaw-bone one and one-half minutes, and for the condyles of the femur eight minutes. At 2 cm. distant the temperature is only 45 to 50 C., and at 3 cm. distant from 35 to 40 C., so that the effect of the steam only extends to about 2 cm. from the tumor. If the greater part of the bone is to be sterilized the sterilization must be effected bit by bit, the metal tube being pushed along the bone. It is not necessary to sterilize the front surface of the bone by itself, for it is included in the sphere of activity of the steam which has sterilized the medullary cavity.

Quarterly Journal of Medicine, London

April, VII, No. 27, pp. 209-323

22 Cholesterin: An Account of Its Relations to Pathology and Physiology. J. W. McNee.
23 *Bilateral Salivary Swellings (Mikulicz' Disease). H. Thursfield.
24 *Prognosis of Acute Articular Rheumatism, Special Reference to Cardiac Manifestations. C. G. Kemp.
25 Anaphylaxis and Its Bearing on Medicine. J. McIntosh.
26 Bacterial Endocarditis. I. Simons.

21. **Paroxysmal Tachycardia.**—Four cases of paroxysmal tachycardia are described by Butterfield and Hunt in three of which the heart was examined histologically. In the first case the focus from which the ectopic beats arose was diagnosed as being situated in the ventricles. Post-mortem, the interventricular septum was the site of the most extensive disease. In the second and third cases the tachycardia was supraventricular in origin, in one case being auricular, in the other, either auricular or nodal. In both these cases the most marked lesions were found in the neighborhood of the sino-auricular node. The histologic examination thus confirms the diagnosis made from the electrocardiograms. The fourth case was one of auricular origin; in the intervals between the attacks the patient enjoyed fairly good health.

23. **Bilateral Salivary Swellings (Mikulicz' Disease).**—Clinically, Thursfield says, it is possible to recognize at least eight groups of cases in which bilateral swellings of the salivary glands, either with or without an accompanying enlargement of the lymphatic glands, form the most characteristic symptoms: 1. A congenital, hereditary, or family affection. 2. Mikulicz' disease proper. 3. Mikulicz' disease with involvement of the lymphatic apparatus. 4. Leukemia. 5. Tuberculosis. 6. Syphilis. 7. Gout. 8. Sialodchitis fibrinosa; intermittent or periodic salivary swelling. In addition there are from time to time met with cases which do not appear to belong to any of these groups. The treatment which appears to promise the best results is to remove carefully any possible source of chronic infection, e. g., decayed teeth; to seek to establish the general health; to give arsenic in the largest doses which can be tolerated, and to treat the actual swelling with Roentgen-ray applications.

24. **Prognosis of Acute Articular Rheumatism.**—Kemp claims that 23 per cent. of patients go through one or more attacks of acute rheumatism without any clinical affection of the heart, irrespective of the age when first attacked; 22 per cent. develop signs of carditis in the acute stage, these signs disappearing during convalescence; 18 to 20 per cent. of the cases which develop signs of endocarditis, not clearing up before patient leaves hospital, have no permanent valvular lesion, the murmurs being due to myocarditis, or incompetence from temporary hyperemia of the valves, associated with dilatation. If a synovial membrane can recover, why should not a heart valve, asks Kemp. In 14.5 per cent. of cases with acute rheumatic endocarditis of severe type, the murmurs undergo a change, resulting in the disappearance of one or more of the murmurs, such murmurs being due to associated dilatation. As a rule, the murmurs due to myocarditis are softer in character than those due to valvular disease.

Cases in which the heart is going to recover completely show signs of such recovery within twelve months of the acute attack, though the process may not be completed till some years later. Graupner's test for the estimation of the cardiac efficiency has not been proved to be of any value in enabling one to recognize the presence or degree of cardiac weakening, not appreciable by the methods already in general use. The amount of physical work which each individual can do in earning his or her living is a far more reliable and efficient test of the heart's working capacity.

Archives des Maladies du Cœur, etc., Paris

27 *Endocarditis of the Anemia Type. C. Achard and C. Foix.
28 *Heart-Block from Inherited Syphilis. A. Nanta.
29 *Transient Heart-Block in Acute Infectious Disease. (Bradycardie par block partiel. Dissociation auriculo-ventriculaire transitoire. Troubles du rythme cardiaque chez des malades atteints de rhumatisme articulaire aigu.) L. Gallavardin, Pallasse, D. Routier, C. Esmein, C. Pezzi and E. Donzelot.
30 Changes in Electric Phenomena of the Ventricle in Heart-Block. L. Gallavardin.

27. **Anemia with Endocarditis.**—Achard and Foix compare two cases from their own experience with several similar ones on record, all having in common anemia of or approximating the pernicious type in connection with malignant endocarditis. A streptococcus was responsible for the trouble in one of their cases. An intense anemia in the course of a subcontinuous febrile state, remittent or intermittent, sometimes with long intervals, should suggest the possibility of malignant endocarditis. Their patients were a man and woman of 28 and 26, with extreme anemia, debility, edema and gastro-intestinal derangement, but there were no erythematous spots such as Osler described as the "finger sign." The fever was moderate but highly irregular, with intervals of normal temperature, but the pulse kept at about 120 all the time, even during the intervals. A double aortic murmur of long standing was not modified by the endocarditis in one case; in the other a mitral murmur developed just before death. Otherwise the heart gave little sign of its diseased condition. The clinical picture was dominated throughout by the severe anemia.

28. **Heart Block from Inherited Syphilis.**—The possibility of an inherited taint was not suspected in Nanta's case until the woman was over 20, although she had developed anemia at 7, a suppurating joint affection at 9, and Adams-Stokes syndrome at 11, and at 20 and 22 she gave birth to children dead or dying soon after. Her pregnancies were followed by multiple scattered gummas, some of which suppurated and burrowed deep, confining the woman to bed for three years, rebellious to all forms of treatment until a vigorous course of neosalvarsan and mercury put her on her feet again. Although the jugular pulse was 87 and the apex beat only 29, the patient had always led an active life until the last four years.

29. **Transient Heart Block in Acute Infections.**—In Routier's cases the complete heart-block developed in the course of acute articular rheumatism or pneumonia. In the first case amyl nitrite gave no relief but the heart-block subsided under atropin, and in the second case spontaneously.

38 *Ocular Sympathetic Disturbances. (Le sympathique oculaire.) A. Cantonnet.

35. **Heart Rhythm as Guide for Use of Digitalis.**—Martinet gives a number of diagrams to explain the mechanisms involved in various forms of arhythmia and the effect of digitalis. He summarizes the practical conclusions in the statement that digitalis is formally contra-indicated whenever there is a tendency to heart block, total or partial. It is also generally better to refrain from its use in cases of bradycardia and extrasystoles. It is moderately useful in paroxysmal, emotional or febrile tachycardia, while it may be regarded as almost a specific for tachy-arhythmia from any cause, perpetual, total arhythmia and auricular fibrillation.

38. **The Ocular Sympathetic.**—Cantonnet urges study of the symptoms from irritation or paralysis of the sympathetic innervation of the eye, emphasizing the information liable to be derived therefrom in regard to an affection in the neck, chest, abdomen or spine, of which the oculosympathetic symptoms may be the first warning sign. The paralysis may be preceded by a period of irritation, and may be revealed by exophthalmos or enophthalmos, drooping or retraction of the upper lid, pallor or redness and dryness or moisture of the face. The mydriasis induced by instillation of two drops of a 4 per cent. solution of cocain shows up well any differences between the pupils when they are examined with a dim light eight minutes later. If there

is spasmodic mydriasis from irritation of the sympathetic there will be maximal dilatation after an atropin collyrium and the pupils grow a little smaller under eserin while the reverse occurs with paralytic myosis; atropin causes only slight dilatation and eserin maximum contraction. With paralysis there is also intense mydriasis with the epinephrin test. His personal experience suggests that when the lesion in the sympathetic is in the upper portion, only motor symptoms are observed. When the lesion is below the neck region, vasomotor and secretory disturbances are observed in addition.

41 *Uncontrollable Uterine Hemorrhage in Large Apparently Fibromatous Organ. (Les gros utérus saignants, d'apparence fibromateuse.) F. Lejars.

40. **Camphor in Pneumonia and Pulmonary Tuberculosis.**—Cheinisse reviews a number of articles that have been published in the last year or two on the therapeutic value of camphor. Crouzon advocates adding a little ether to camphorated oil to render it more fluid and thus promote its absorption when injected intravenously; Schule uses ether alone for the vehicle. Subcutaneous injections of camphorated oil have been applied with apparent success in pneumonia by four Russian physicians and by several in Germany. Evidence is accumulating that camphor has a bactericidal action on pneumococci. Hötzel injected subcutaneously twice a day 10 c.c. of camphorated oil in thirty cases of pneumonia and is convinced that it had a specific action. The pneumococcus cannot be cultivated on culture medium containing 1 per ten thousand camphor. Rabbits inoculated with the pneumococcus were saved by a series of subcutaneous injections of camphor without which the controls died. Weihrauch ascribes the antipyretic influence of camphor to its bactericidal action on the mixed infection. When in pneumonia the heart action is good, Svoiekhotov gives the camphor by the mouth every two hours up to the crisis and then at longer and longer intervals for a few days. If the pulse is already up to 120, he begins at once with subcutaneous injections of camphorated oil.

41. **Abnormal Uterine Hemorrhage without Fibroma or Cancer.**—Lejars compares with his own experience the findings recently reported by Briggs and Hendry in 104 uteri after hysterectomy for uncontrollable hemorrhage. They found pedunculated adenomas in fifteen and sessile adenomas in five, and Lejars expatiates on the disturbance liable to be set up by a little tumor of this kind. It acts like a foreign body and tends to induce hypertrophy. In one such case a large median tumor could be felt above the pubis and supravaginal amputation was done as the only measure appropriate for the supposed fibroma. Nothing of the kind was found, however; merely a small polyp implanted in the fundus. The thickened and congested wall had simulated a fibroma on palpation. In a quite recent case a woman of 49 had severe hemorrhages and pain persisting outside of the periods of hemorrhage, with extreme pallor and anemia. The uterus was large as a man's fist but movable, and he removed it as a typical fibromatous organ. The surface proved to be smooth and there were no fibromas except a minute one, very low down. But the uterine wall was abnormally thick and large, measuring almost 5 cm. The mucosa was thickened and edematous. A pedunculated polyp grew near the fundus and a sessile polyp low down. The practical importance of such cases is that examination of the interior will disclose the polyp, and its removal will obviate the necessity for a more serious operation when the woman is still in the child-bearing age. The perfect regularity of the surface of the uterus and its uniform consistency are the only findings which cast a doubt on the assumption of a fibromatous uterus as the explanation of the hemorrhages.

42. **Inspection and Palpation of the Chest.**—Galecki tabulates his findings in 300 cases of pulmonary tuberculosis omitting his first 150 cases. He noted a sinking in of the chest wall and of the supra and subclavicula fossae in 43.6 per cent. of the chronic cases in the first stage; in 50.5 in the second and 48.6 in the third stage, confirming the occurrence of this sign with chronic shriveling processes in the lung. The shoulder on the affected side was lower than the other in 190 cases, that is, in 63 per cent. Kuthy's acromion sign was evident in 81 per cent. of all the patients, and in 75 per cent. of the quite recent cases. This sign consists in the lagging behind or total lack of movement in the acromion, the point of the shoulder, as the patient takes a deep breath. Galecki regards this sign as extremely instructive and important, especially when both shoulders present it. He regards it as the most characteristic and striking sign of pathologic interference with the respiratory movements. He found it marked in 69.6 per cent. in the first stage, in 81.9 in the second and 91 in the third, but it gives no hint as to the nature of the process in the lung. He found a difference in the excursions of the ribs on the two sides only in 39 per cent. and mostly in the third stage of the disease. Rigidity of the muscles over the affected area was found in 93 per cent. of the recent cases and not at all with extinct foci. Between these extremes he noted the abnormal local tonus in the muscle in 67 per cent. Local atrophy of muscle was apparent in most of the old chronic cases, corresponding to some degree in extent with the process in the lung. Light touch palpation gave positive findings in 245 of the 346 lung processes with rigid muscles above, but only in 21 of the 132 without local rigidity. Dilated veins were found unreliable as a sign of a pulmonary process.

45. **Research on the Tuberculin Reaction.**—Klemperer found it impossible to render non-tuberculous animals susceptible to tuberculin by preliminary treatment with tuberculin. He concludes from this that the reaction to tuberculin is not a phenomenon of anaphylaxis. He reports further that animals with a local tuberculous process lose their susceptibility to tuberculin for a time after the local process is excised. This seems to demonstrate that the tuberculin reaction is not due to antibodies circulating in the blood. He gives the tracings and tabulated details of his experiments on rabbits and guinea-pigs and some clinical experiences.

46. **Skin Tuberculin Test, Both Human and Bovine.**—Nothmann applied the Pirquet test with both human and bovine tuberculin to 207 children. A negative response was obtained to both in 27 per cent.; 64.2 per cent. reacted positively to both; 0.97 to the bovine alone and 4.3 to the human alone, and 0.5 per cent. to first one and then the other. The significant fact was observed that a reaction to both was obtained at a single trial only in 82.1 per cent. while at the second or third test 91.7 per cent. gave a positive reaction.

52 *Collective Inquiry on Goiter. W. V. Simon.
53 *Experimental Rachitis. J. Koch. Commenced in No. 17.

52. **Collective Inquiry on Goiter in Silesia.**—Simon here gives the conclusions drawn from the question-blanks sent to all medical men in Silesia and returned by nearly all, carefully filled out. Twenty-two questions were asked in regard to the prevalence, age incidence, etc., of goiter in each physician's district. A total of 251 cases of goiter were thus listed and a number of goiter nests were discovered. A connection with the drinking water seems more plausible on analysis of the data than the assumption of contact transmission.

53. **Experimental Rachitis.**—Koch injected the *Streptococcus longus* into young animals and an acute infection followed at once, gradually entailing a chronic disease of the bones which apparently was the same as rachitis in man. The dogs allowed to run about freely did not develop the bone trouble or not in the same degree as the dogs kept in stalls. Domestication undoubtedly favors the development of the disease. His experience confirms further the injurious influence of secondary infection after the process of normal ossification had once been upset by the acute infection. The ossification centers are for a long time in a condition of lessened resistance, and an intercurrent whooping-cough, chronic enteritis or the like adds further fuel to the flame. According to his experience, the injurious influence of infections alone—without calling on metabolic derangement—is enough to explain the trouble. Further research will show whether the *Streptococcus longus* alone is capable of this malign influence on the ossification centers or whether other germs may be involved. The pathologic changes in the skeleton after acute infectious diseases in children will repay study, and much may be learned from the veterinarians in this line.

69 Organic and Mental Development. S. Meyer.

58. **Otosclerosis.**—Denker says that all the mechanical and local operative measures that have been applied to cure otosclerosis have given such poor results that he cannot recommend any of them, particularly as an aggravation of the deafness from their action lies well within the possibilities. Of internal measures, Politzer advises 1 gm. of potassium iodid daily for ten or fifteen days, repeating this four or five times a year. Some have reported benefit from thyroid treatment; others have been less fortunate with it. Denker had found phosphorus useful, alone or combined with bromid. The progress of the deafness was often arrested and the subjective noises subsided. Patients with otosclerosis should be urged to take a course in lip-reading before the hearing is entirely lost. The main point with otosclerosis is prophylaxis. It has a pronounced familial and hereditary tendency, and is liable to increase in severity during periods of special stress and more active bone growth, as at puberty and during a pregnancy. Derangement of the circulation, as with vasomotor neuroses, syphilis and arteriosclerosis, may also contribute. The physician should warn with special emphasis against the intermarriage of persons with a tendency to otosclerosis. They should guard against catching cold and should avoid cold douches on the head and keep away from the seashore. The question of preventing conception should also be considered, as pregnancy usually brings an aggravation of the trouble.

76 Influence of Radio-Active Substances on Immune Serums and Infected Animals. J. Kemen and F. Diehl.
77 *Reaction to Luetin is Specific for Syphilis; the Wassermann Reaction Not Specific. (Ueber Lues.) H. Much.

71. **Paresis.**—Pilcz regards progressive paralysis as more than an affection of the brain alone; the cerebral-nervous symptoms are merely one element in the syndrome. This has been established beyond question, he says, by the positive findings with the Abderhalden test in respect to kidney, heart, spleen and liver tissue in addition to brain tissue. The predisposition to paresis may lie in the individual or in the special strain of spirochetes or in climatic or other modifications of the spirochetes, or in all these factors combined; "paralyticus nascitur et fit." The assumption of an individual predisposition is sustained by the frequent observation that the persons who develop paresis had an unusually mild form of syphilis in its earlier stages, showing an inherent abnormal mode of reaction to the infection. Pilcz cites recent authorities who announce that paresis seems to be becoming more prevalent in tropical countries and Japan, and also cases of conjugal progressive paralysis and tabes are becoming more frequent everywhere. Further experience is confirming also the lack of any febrile affection after the syphilis was acquired, in the history of a long series of patients with paresis, while a history of some febrile infection was almost invariably encountered among their syphilitic mates who had escaped progressive paralysis. This is the basis of von Wagner's tuberculin-fever therapy in treatment and prophylaxis of paresis, and Pilcz reiterates that favorable reports on this are accumulating from Tamburini and Battistessa in Italy, Siebert and Glouschkoff in Russia, Hudovernig and Wachsman in Hungary, and Meyer, Friedländer, Röper and Pilcz himself in Germany and

Austria. The fever therapy with staphylococcus vaccine, with nuclein or salvarsan might be usefully combined with the tuberculin-fever therapy. Nonne emphasizes the logical favorable action of the induced febrile reaction with its leukocytosis now that Noguchi has shown that the spirochetes in the brain lie in tissues which otherwise are almost entirely reactionless.

77. **The Luetin and Wassermann Reactions as Guides to Treatment.**—Much summarizes his conclusions from study of these reactions in syphilis in the statement that when it is a question of ascertaining whether the patient has ever had syphilis, the response to the luetin test is most instructive. But when it is a question of ascertaining whether the organism is still under the influence of the syphilis toxin, then the Wassermann test is more instructive. As a guide to treatment, the effort must be made to render the Wassermann negative, as this is a manifestation of destruction of tissue. On the other hand, the luetin reaction—as the expression of production of specific immune bodies—should be kept positive.

81 Embolic Aneurism as Complication of Acute Endocarditis. O. Lindbom.

78. **Enhanced Resistance of the Peritoneum in Acute Appendicitis.**—Solieri was a pioneer in efforts artificially to increase the resisting powers of the peritoneum preliminary to operations and in treatment of acute infections. Various chemicals have been used to rally the phagocytes in the region, but his experimental work seems to have demonstrated that a sterile culture of the colon bacillus is by far the most efficient of all substances tested to date to accomplish this purpose. Preventive injection into the guinea-pig peritoneum enhanced twenty-fold its resisting powers against living and virulent cultures of the same species. On this basis he assumed that the colon bacillus toxin already in the peritoneum in acute appendicitis would answer the purpose of a preliminary treatment from without, attracting the phagocytes and generating agglutinins, and consequently that after excising the appendix the peritoneum can be left tranquilly unmolested from without, leaving the appendicectomy incision completely sutured, without draining, when there is reason to assume the organism is capable of vigorous phagocyte action and agglutinin production. After removal of the disease focus in the appendix the peritoneum, under the influence of the colon bacillus toxin, finds its resisting powers so enhanced that it needs no further aid from without. In a series of 336 acute appendicitis operations he found only twenty-seven cases in which the conditions were favorable for this, namely, the patients were young and vigorous; they had had previous attacks of appendicitis testifying to abundant bacillus-toxin production; the delay before operation was not over twelve to forty-eight hours after the first symptoms; the blood showed pronounced leukocytosis and pronounced reaction to the Rivalta serum test; there was also considerable febrile reaction; the pulse was strong and regular; the urine showed that the kidneys were in good condition; there were no signs of other disease, and the appendix had not perforated and the reaction of the peritoneal serosa, as estimated during the operation, was regarded as adequate for the purpose. The details of the series are tabulated, all showing rapid and complete recovery and almost invariably by primary intention.

79. **Connection between Organic Changes in the Brain Cortex and Symptomatic Epilepsy.**—Denk gives an account of considerable experimental work on dogs and rabbits and analysis of 33 clinical cases of brain tumors, only 5 of which were without epilepsy, and 28 cases of epilepsy with operation or necropsy findings in nearly all. All this material is sifted and compared, and certain common traits are thus rendered evident. Aseptic organic changes in the brain do not seem able of themselves to induce epilepsy. There is always some accessory factor in the cases in which the epilepsy develops. This may be an inherited predisposition; this alone is liable to be enough to start the epilepsy without any organic changes. Alcoholism is liable to be the subsidiary factor which, superposed on the organic changes, may bring on the epilepsy even in the not otherwise predisposed. Tumors, inflammation and mechanical irritation may bring it on with a natural predisposition. The cicatrix from an operation is liable to induce epilepsy when superposed on alcoholism or a predisposition, even in cases in which there had been no tendency to epilepsy before the operation on the brain. The above conclusions impose the necessity for an early operation without delay when internal measures have failed, seeking to forestall the development of extensive pathologic changes in the brain. Another practical conclusion is that it is immaterial what living material is selected to close defects in the skull and interpose between tissues; all are absorbed in time, whether dura, fascia or other living material is used. The favorable reports from plastic operations of the kind with dura are the result, Denk insists, of the buffer action of the interposed tissue as long as it persisted, the blood drawn during the operation and the manipulation of the cortex.

95. **Treatment of Bronchiectasia and Chronic Bronchitis.**—Singer is enthusiastic over the benefit derived in cases of this kind from reduction of the intake of fluids. The expectoration decreased at once and with it the cough in cases of chronic bronchitis and purulent bronchiectasia. The

patients are given abundance of mixed food but the total amount of fluid in the twenty-four hours, in soups, beverages, etc., is restricted to 600 c.c. On the fourth day the patient is encouraged to drink at will, thus thoroughly flushing out the system. Then he is restricted anew in the intake of water, down to 400, 300, or 200 c.c. for the next three days. It is sometimes advantageous to give in the form of wine the quantum of fluid allowed.

Slices of lemon or orange also help to quench the thirst, and certain bonbons. The thirst may also be combated by a sedative taken into the stomach, but he was very seldom compelled to resort to these measures. When the patient once gets accustomed to the restriction he can keep it up for weeks without discomfort or harm; the interposed days of unlimited fluid intake twice a week keep the system washed out so there seems to be no danger of uremia, etc. Brauer and Hochhaus also report gratifying results. Singer has seven patients who have been completely cured for two years, and a number of others keep in clinical health by repeating the "thirst cure" for several weeks two or three times a year. No by-effects were ever observed. In the majority of cases the patients gain from 20 to 25 pounds in a few weeks as the drain from the sputum production stops. Certain forms of pulmonary tuberculosis accompanying the chronic bronchitis seem to be benefited along with the latter by the thirst cure. An unsuspected suppurative process in the maxillary antrum kept up the bronchitis in one case until it was discovered and cured after which the bronchitis rapidly subsided under the restriction of fluids. A syphilitic factor does not interfere with the treatment and the latter does not exclude application of superheated air and other measures, including calcium, and inhalation of oxygen to combat putrefaction bacteria.

He has found the "thirst cure" effectual also in a number of cases of asthma long rebellious to all other measures. He regards asthma as a manifestation of the constitutional tendency known as the exudative diathesis. The transudation of fluid into the bronchi is an important element in the clinical picture of asthma, and this element can be abolished by restricting the intake of fluids. His theory that the "thirst cure" modifies osmosis has been confirmed by his findings in six cases after intravenous injection of a hypertonic salt solution. This had the same only a much more intense effect than restriction of fluids. Even slight changes in the concentration of the body fluids and serum suffice to attenuate or arrest completely the paroxysmal or continuous flooding of the bronchi with fluid. When this is accomplished, he adds, there is no further asthma, bronchitis heals, and the suppuration in bronchiectasia ceases.

96. **Benzol in Leukemia.**—Liberow reports a case showing an unmistakable improvement under benzol but he warns that it should not be given except with constant oversight over the blood and urine. He did not give large doses, keeping usually at 2 or 1.5 gm. When the leukocytes had dropped to 13,000, he reduced the dose still more, so that there was no further decline of leukocytes and the reds rose and kept above 5,000,000, the hemoglobin at 62 per cent. The patient was a woman of 34 with extreme ascites, probably from pressure on the portal vein by a leukoma; as the latter subsided under the influence of the benzol the circulation grew better and the ascites disappeared.

100. **Treatment of Associated Gout and Diabetes.**—Von Noorden states that in his experience with 6,000 diabetics in the last twenty years he has encountered scarcely a dozen with actually severe gout. As a general thing, associated gout and diabetes are both in a mild form, but there seems to be a special liability to serious complications: cardiovascular or kidney disturbance, cataract, retrobulbar optic neuritis, neuralgia and neuritis. The two last are most common and severe. The physician is apt to regard these painful affections as the work of the gout, and consequently directs treatment at the gout, when in reality hyperglycemia is responsible for the neuralgia and neuritis in most cases. This is what should be combated; the gout can be disregarded; the main point is to put the patient on an antidiabetic diet. Under this the glycosuria rapidly subsides; the hyperglycemia persists much longer—longer under these conditions than otherwise. But rebellious and chronic neuralgia, especially sciatica, can be cured in this way in the course of a few weeks when previously all kinds of treatment had given only transient improvement at best. The manifestations of the gout and any kidney trouble improve on the antidiabetic diet; it may be advantageously supplemented by physical measures when the hyperglycemia has subsided. This cannot be anticipated until after four or five weeks. To keep the patient in good condition afterward, at least on one day a week he should refrain from purin and carbohydrate food and every second month should have a purin-free two-week period. If the gout and diabetes are both severe he advises a diet to combat each in turn for two weeks. In conclusion he warns that persons with both gout and diabetes are unable to tolerate colchicum preparations as a rule.

102. **Possible Dangers from Confusion of Names of Proprietaries.**—Heubner remarks that manufacturing chemists seem to be running out of names for their productions, as so many of the new names are the same except for the change of a letter or two. Rabow, writing recently in the *Chemiker Zeitung*, comments that the handwriting of physicians is not always very distinct, and when medicines have closely similar names there is liable to be confusion. Heubner cites as examples "the laxative Darmol; the sedative, Dormal; the wood-preserving mixture, Dormial; the hypnotic Dormiol and the remedy Dormonal; the hypnotic, Chinoral; the internal antiseptic, Chinorol; the external antiseptic, Chinosal, and the remedy Chineonal."

108 *Favorable Effect of Intravenous Injections of 10 per cent. Salt Solution to Arrest Hemoptysis. J. Moczulski.
109 Suggestions for Internal Equipment of Hospitals. M. Setz.

106. **Treatment of Leukemia.**—Pulawski's case of lymphatic leukemia emphasizes the importance of combining roentgenotherapy with benzol. His patient was a woman of 51 who for two years had had enlargement of lymph-nodes in various regions and an abdominal tumor. Her present complaints were of sacral pains and pain in the left abdomen, weakness and cough, with signs of mild kidney trouble and the blood findings typical of lymphatic leukemia. Under six Roentgen exposures in nine days the whites dropped from 425,600 to a third; this was followed with 50 gm. benzol in sixteen days and the whites dropped to 8,400. There was some fever during the last week or so of the benzol course. Then the Roentgen exposures were resumed, four being given in nineteen days. After suspension of the benzol the whites continued their decline, finally reaching 1,100 and then 2,600 by the end of the three months' course of treatment. The general condition has continued to improve as well as the blood-picture, the lymphocytes dropping from 90 to 41 per cent., the neutrophils climbing from 10 to 49 per cent. The lymph-nodes have returned to normal size and the spleen to a quarter of its first size. The anemia was quite pronounced when the benzol course was concluded, but improved under iron, arsenic, calcium glycerophosphate and cod liver oil.

107. **Radium Emanations for Leg Ulcer.**—Saphier states that in ten of twenty-one rebellious cases of old leg ulcer a complete cure was realized under a course of radium emanation treatment. Material benefit was realized also in six other cases. No effect was apparent in five.

108. **Hypertonic Saline Infusion for Hemoptysis.**—Moczulski states that in nine cases of hemorrhage from the lungs

the tendency to hemoptysis was favorably influenced by intravenous infusion of 10 c.c. of a 10 per cent. salt solution. The effect is not apparent at once and it does not protect against recurrence of the hemoptysis. No influence was apparent in purpura and other hemorrhagic affections.

114 Epigastric Hernia. N. Federici.
115 Cysts of the Spermatic Cord Originating in Connective Tissue. R. Mosti.

113. **Electric Currents and the Blood-Pressure.**—Fontana comments on the contradictory experiences related by different clinicians in respect to the action of the high frequency currents on the blood-pressure, some reporting considerable reduction in abnormally high pressures while others have observed nothing of the kind. He had similar contradictory experiences himself and he set out to discover the cause for this variability in the action of the currents. Analyzing forty-seven cases he found that the blood-pressure was constantly reduced when the kidneys were normally permeable, but that they failed in this influence when the kidney functioning was below par. The current causes slight dilatation of the vessels, and this in connection with the stimulation of metabolic processes which it induces, causes a throwing off of waste products through the kidneys if they are equal to this task. The result is a marked drop in the blood-pressure. The outcome therefore depends on the permeability of the kidneys.

122 *The Liver in Chronic Malaria. (O figado no paludismo chronico.) C. Fraga.

122. **The Liver in Chronic Malaria.**—Fraga's extensive experience with chronic malaria has demonstrated that this disease has a tendency to spare the liver. True malarial disturbances in the liver are comparatively slight. The cirrhosis of the liver so often encountered in chronic malaria is due mainly to the same causes, alcoholism, etc., which induce it under other conditions. The anemia in chronic malaria is often due to helminthiasis which is particularly prevalent in the malaria zones. His functional tests applied to the liver in chronic malaria, including the alimentary lipemia or hemoconiae test, all revealed merely comparatively slight disturbance in liver functioning, curable by the ordinary measures.

133 Anthropologic Research on Island Near Sumatra. J. P. K. de Zwaan.
134 *Prevalence of Tuberculosis among the Elderly with Bronchitis. J. Sanders.

124. **Familial Orthostatic Urobilinuria.**—Steensma gives a family chart through five generations with sixteen members who have orthostatic urobilinuria: that is, there is urobilin in the day urine and not in the night urine. Somewhat similar findings were encountered in a second family. He thinks that there must be a family tendency in these cases for the ductus venosus not to become impervious as under normal conditions. The patent duct would permit some of the blood from the intestines to get into the blood stream without passing through the liver.

132. **Tardy Complications after Reduction of Congenital Hip Joint Disease.**—Redard refers to the development of ostitis or osteomalacia in the joint after apparently successful reduction of congenital dislocation. Five, eight or ten years later a tendency to coxa vara may become apparent, with more or less atrophy and deformity of the head and upper end of the femur. The ossification centers probably were injured to start with. Such cases teach the necessity for keeping patients long under supervision and not to have the immobilizing appliance worn too long, not over six months at most.

134. **Tubercle Bacilli in Apparently Non-Tuberculous Elderly Persons.**—Sanders examined the sputum of all the inmates over 60 years old of a Rotterdam hospital who were apparently free from tuberculosis but had signs of chronic bronchitis. He obtained sputum in thirty-nine cases and found tubercle bacilli in them in nine. This shows that the apparently harmless bronchitis of the elderly may be an unsuspected source for infection of others.

HOOKWORM DISEASE

ITS RAVAGES, PREVENTION AND CURE *

JOHN A. FERRELL, B.S., M.D.
Assistant Administrative Secretary, Rockefeller Sanitary Commission
WASHINGTON, D. C.

Hookworm in sections in which it prevails is one of the most common, most insidiously harmful, and most easily prevented diseases known to man. It causes human suffering and economic waste altogether out of proportion to its apparent death-rate. Many ills which have been attributed to mental and moral weakness of whole bodies of people are now definitely known to be due to this infection, and curable with its cure. Its eradication is one of the most important and pressing problems before the people of the southern half of the United States and of other semitropical and tropical lands. Moreover, the progress which has been made in recent years completely demonstrates at once the vast benefit, in terms both of human happiness and of industrial efficiency, attendant on stamping out of the disease, and also the complete adequacy, in stamping it out, of perfectly simple precautions prescribed by the primary rules of health and even of common decency.

WHERE HOOKWORM DISEASE IS FOUND

Hookworm disease is found more or less prevalent in the entire zone lying within 30 degrees north and 30 degrees south of the equator, or in practically all the tropical and semitropical countries, in which are more than half the people of the globe. In many of these countries this anemia-producing infection is extremely prevalent, in a severe form. In Porto Rico and the low-lying districts of Colombia, and in many of the sugar plantations of Ceylon and Dutch Guiana, for example, infection was found to involve 90 per cent. of the entire population. Since 1904 more than 300,000 persons have been treated for hookworm disease in Porto Rico, with the result that, whereas in 1900 and 1901 the deaths from anemia numbered 11,875, or 33.2 per cent. of the total deaths in the island, and in 1902 and 1903, after some treatent for hookworm, 6,830; they had fallen in 1904 and 1905 to 4,693, and continued to decrease until they were in 1906 and 1907 only 1,134, and in 1907 and 1908, 1,785. The majority of Porto Ricans, long noted for laziness and shiftlessness because of this anemia, are now known to have been the victims of a specific infectious disease; the wholesale treatment of which is revolutionizing the island, and bringing health and prosperity where almost universal misery and poverty reigned.

In the United States, the disease is found throughout the states south of the Potomac and Ohio rivers, in Arkansas, Missouri, Oklahoma, and Texas, and also in California. Its prevalence and severity vary widely within the state and even in a county, in some localities less than 1 per cent. of the people being infected, and in others more than 90 per cent. Generally speaking, the heaviest infection is found on the light, sandy soil of the coastal plains, the lightest infection on the stiff, clay soil of the Piedmont region, and an intermediate infection among the foothills and mountains. It is peculiarly a disease of the agricultural districts, which goes far to explain the long-puzzling lack of physical and intellectual vigor to be noted among large classes of people in what ought to be one of the healthiest and most prosperous sections of the country (Figs. 1, 2 and 3). Examination of more than 415,000 school children during the four years 1910-1913 in 413 counties of the eleven Southern states has revealed 43 per cent. of them infected. Of more than 700,000 persons of all ages taken at random in the same territory, 35 per cent. were found to be suffering from this disease, and in a vast majority of cases were completely cured.

When individual treatment has been accompanied by simple sanitary reforms to prevent reinfection, most noteworthy benefits have been derived by entire communities. For example, in the camps of the Continental Coal Corporation, at Pineville, Ky., where 1,800 men were on the company's pay-rolls, in June, 1911, about 65 per cent. were infected with hookworm, there were about 150 cases of typhoid, and cases of bowel complaint were numerous. Soil pollution through lack of sanitary water-closets was practically universal, the water-supply was contaminated, and flies had free range. Measures were taken to eradicate the hookworm by providing sanitary closets, which stopped soil pollution and prevented flies from carrying the infection back into the houses, and the water supply was also safeguarded. As a result, in the year following, the same force of men loaded over 33 per cent. more coal on the cars than they did in the year before. Also there was not a single case of typhoid in [illegible] camps during the summer of 1912, and cases of [illegible]rhea were reduced to about one-half.

HOW THE HOOKWORM AFFECTS ITS VICTIMS

For generations hookworm disease has [illegible]iously spreading unrecognized and unch[illegible] countries of the globe having a mild c[illegible] have [illegible] tims, numbering many millions.

HOOKWORM DISEASE

ITS RAVAGES, PREVENTION AND CURE *

JOHN A. FERRELL, B.S., M.D.
Assistant Administrative Secretary, Rockefeller Sanitary Commission
WASHINGTON, D. C.

Hookworm in sections in which it prevails is one of the most common, most insidiously harmful, and most easily prevented diseases known to man. It causes human suffering and economic waste altogether out of proportion to its apparent death-rate. Many ills which have been attributed to mental and moral weakness of whole bodies of people are now definitely known to be due to this infection, and curable with its cure. Its eradication is one of the most important and pressing problems before the people of the southern half of the United States and of other semitropical and tropical lands. Moreover, the progress which has been made in recent years completely demonstrates at once the vast benefit, in terms both of human happiness and of industrial efficiency, attendant on stamping out of the disease, and also the complete adequacy, in stamping it out, of perfectly simple precautions prescribed by the primary rules of health and even of common decency.

WHERE HOOKWORM DISEASE IS FOUND

Hookworm disease is found more or less prevalent in the entire zone lying within 30 degrees north and 30 degrees south of the equator, or in practically all the tropical and semitropical countries, in which are more than half the people of the globe. In many of these countries this anemia-producing infection is extremely prevalent, in a severe form. In Porto Rico and the low-lying districts of Colombia, and in many of the sugar plantations of Ceylon and Dutch Guiana, for example, infection was found to involve 90 per cent. of the entire population. Since 1904 more than 300,000 persons have been treated for hookworm disease in Porto Rico, with the result that, whereas in 1900 and 1901 the deaths from anemia numbered 11,875, or 33.2 per cent. of the total deaths in the island, and in 1902 and 1903, after some treatent for hookworm, 6,830; they had fallen in 1904 and 1905 to 4,693, and continued to decrease until they were in 1906 and 1907 only 1,134, and in 1907 and 1908, 1,785. The majority of Porto Ricans, long noted for laziness and shiftlessness because of this anemia, are now known to have been the victims of a specific infectious disease; the wholesale treatment of which is revolutionizing the island, and bringing health and prosperity where almost universal misery and poverty reigned.

In the United States, the disease is found throughout the states south of the Potomac and Ohio rivers, in Arkansas, Missouri, Oklahoma, and Texas, and also in California. Its prevalence and severity vary widely within the state and even in a county, in some localities less than 1 per cent. of the people being infected, and in others more than 90 per cent. Generally speaking, the heaviest infection is found on the light, sandy soil of the coastal plains, the lightest infection on the stiff, clay soil of the Piedmont region, and an intermediate infection among the foothills and mountains. It is peculiarly a disease of the agricultural districts, which goes far to explain the long-puzzling lack of physical and intellectual vigor to be noted among large classes of people in what ought to be one of the healthiest and most prosperous sections of the country (Figs. 1, 2 and 3). Examination of more than 415,000 school children during the four years 1910-1913 in 413 counties of the eleven Southern states has revealed 43 per cent. of them infected. Of more than 700,000 persons of all ages taken at random in the same territory, 35 per cent. were found to be suffering from this disease, and in a vast majority of cases were completely cured.

When individual treatment has been accompanied by simple sanitary reforms to prevent reinfection, most noteworthy benefits have been derived by entire communities. For example, in the camps of the Continental Coal Corporation, at Pineville, Ky., where 1,800 men were on the company's pay-rolls, in June, 1911, about 65 per cent. were infected with hookworm, there were about 150 cases of typhoid, and cases of bowel complaint were numerous. Soil pollution through lack of sanitary water-closets was practically universal, the water-supply was contaminated, and flies had free range. Measures were taken to eradicate the hookworm by providing sanitary closets, which stopped soil pollution and prevented flies from carrying the infection back into the houses, and the water supply was also safeguarded. As a result, in the year following, the same force of men loaded over 33 per cent. more coal on the cars than they did in the year before. Also there was not a single case of typhoid in the camps during the summer of 1912, and cases of diarrhea were reduced to about one-half.

HOW THE HOOKWORM AFFECTS ITS VICTIMS

For generations hookworm disease has been insidiously spreading unrecognized and unchecked over the countries of the globe having a mild climate. Its victims, numbering many millions, have through centu-

---

* This paper is one of a series on Public Health, prepared at the request of the Council on Health and Public Instruction, and reprinted for distribution to the public through state boards of health and other agencies. Other articles are being prepared and will be issued later. A list of the pamphlets can be secured from the Council on Health and Public Instruction, American Medical Association, 535 North Dearborn Street, Chicago.

ries, no doubt, been hosts to the small blood-sucking intestinal parasite which causes the disease. Their strength has been sapped, their vitality lowered, their physical and intellectual growth stunted. They have been mastered in war, commerce and industry by the more hearty people of colder latitudes to the north. The social and economical importance of the disease is therefore almost beyond comprehension. The infection is in most instances so insidiously acquired by the unsuspecting victim that he and the members of his family, who are probably likewise being infected, do not know just when the effects of the disease began to manifest themselves. In the course of a few summers, however, a once healthy family has become pale and puny; a once industrious family has become languid and backward in its work; a once prosperous family has fallen into debt; a once proud family, owning valuable property, has been reduced by an easily curable and easily preventable disease to tenancy and to poverty. The children, once bright and well advanced in their school classes, begin to lose their zeal and their mental alertness when gradually robbed of their vitality. They fall behind in the struggle with their healthier classmates, and, finally discouraged and perhaps abused, give up school work in despair.

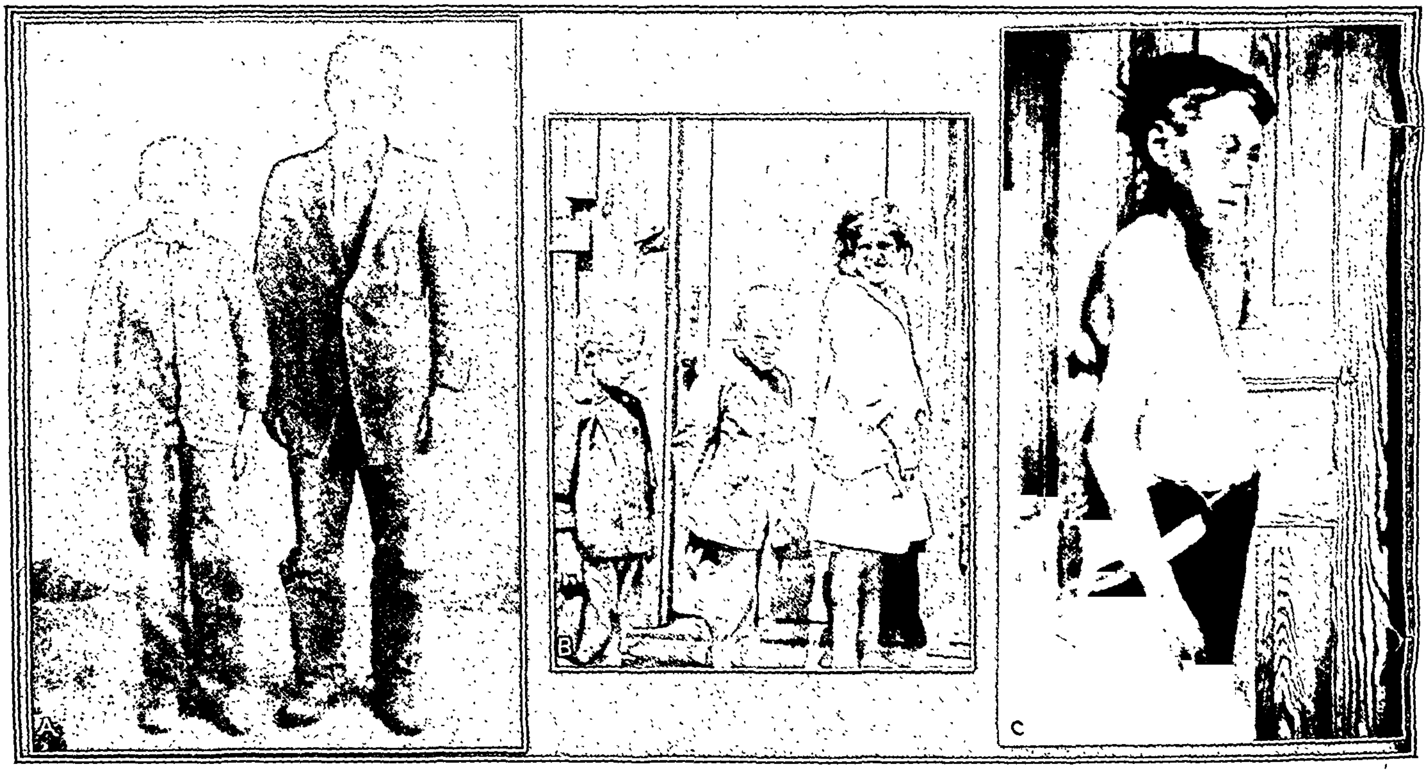

Fig. 1.—Effects of hookworm disease: *A*. Small boy is H. M. of Heber Springs, Ark., called "Chalky" from the extreme pallor of his face. "Chalky" is 18 years old, weighs 82 pounds, and uses chewing-tobacco, snuff and profane language. He is uncle of the larger boy, is two months older and 50 pounds lighter than his nephew, who is not infected. *B*. Three heavily infected children, aged 13, 9 and 7 years, of Wise County, Va. The boy was treated for consumption. Twenty grains of thymol brought 234 hookworms, a dwarf tapeworm and almost complete recovery. *C*. Boy, I. S., of Stokes County, N. C., severely infected. Note the "angel wings" shoulder-blades and the "pot-belly," characteristic symptoms.

GREAT ECONOMIC LOSS DUE TO THE HOOKWORM

This is no exaggerated picture of the harm wrought by the disease. The economic loss already stated in the case of the Kentucky coal-miners is to be found wherever the disease prevails. The physically sound coffee-picker in Porto Rico picks from 500 to 600 measures of coffee a day. Dr. Wickliffe Rose reports that he found scores of infected men there who could pick only from 100 to 250 measures a day, and the manager of one of the great haciendas, or plantations, told him that the disease had reduced the average efficiency of labor on the coffee estates to from 35 to 50 per cent. of normal. One of the largest cocoa plantations in Ecuador reports that 300 laborers on the place were so reduced by the anemias of hookworm and malaria as to be able to do not more than one-third of a reasonable day's work. The manager of a large British Guinea sugar estate reports that treatment for hookworm has doubled the working power of the gangs. A single California mine employing over 300 men is estimated to have lost 20 per cent. of the wages paid, or $20,000 a year, because it had to carry on the pay-roll a large body of men to replace those periodically unable to work because of hookworm anemia. In the South Atlantic and Gulf states the infection is heavier than in California, and the loss on the farms and in the cotton factories is enormous. The weavers in the Southern mills are not naturally inferior to the European immigrants who operate the New England looms. Their labor is less efficient in some instances because vast numbers of them are victims of the hookworm. The Southern farms are not lacking in fertility, nor are their owners, whose fathers fought under Lee and Jackson, lacking in sterling virtues; but thousands of men and women with the best blood of the land in their veins are made improvident and slothful by this infection, and the hundreds of cases in which these supposed faults of character have been reformed by hookworm treatment prove beyond question the enormous moral and economic cost of the disease.

GROWTH OF CHILDREN RETARDED

Hookworm retards the development of children to a remarkable degree. School and college records show that infected students, even though not apparently ill, average lower in their studies than those found free from infection. In one woman's college the average standing of fifty-six girls found infected was 77.75 per cent., whereas fifty-six girls taken at random from those in the institution found free from infection averaged 89.28 per cent. Similarly in an academy, a group of twenty-five infected men and boys averaged 64 per cent., and a non-infected group beside them averaged 86 per cent. Teachers in all parts of the South report marked improvement in zeal and intelligence, as well as in weight and physical appearance of children immediately on being freed from the parasites. One case from the field director of the hookworm campaign in Prentiss County, Miss., may be given as fairly typical of the experience of physicians in this work.

> "A young man that we treated furnished us the best recommendation that we could have had. He came to the office about the third week looking as if he had an advanced case of tuberculosis, and with a cough that appeared serious. He was such a picture of dejection, misery and lost hope, that he attracted the attention of the whole court-house crowd and many of them watched eagerly to see the results of the examination. One man asked me after he left, if I could cure him, and I replied that we would do our best. This man then kindly stated that he thought that I was doing the boy an actual wrong by holding out hope, as it was his belief that the boy would die in a very short time. This boy was instructed to return every week for his treatment until informed that he was cured. He did; and it was a standing request by the court-house officials that they be called each week as W. L. came in, so that they could see for themselves whether he was improving or not. On his first trip, one week later, he came in, and there was evidence of much improvement. He came in with a smile, showing more interest in things around, telling jokes to fellows in the office, when just one week before he had stood listless without a word to any one except to answer 'yes' or 'no' when a question was put to him. He informed us that on this trip, although he had taken his medicine only a week ago, he was feeling a great deal better; and when placed on the scales, I found that he had gained a number of pounds in weight. He was given three treatments, one week apart, and after waiting two weeks following the third treatment, he was found free from infection, and weighed 18 pounds more than he did previous to the first treatment. On the day that he first appeared at the dispensary he could hardly walk, and the last time that I saw him he started with another boy to walk 7 miles to his home."

THE PENALTY OF IGNORANCE AND NEGLECT

Such facts, of which hundreds of the same import might be cited, show the heavy price which the people of the South have been paying in loss of money, health and intellectual power, for ignorance and carelessness concerning a disease which is easily diagnosed, easily cured and easily prevented. It is due solely to neglect of sanitation which permits the eggs of the small intestinal worms which pass with the excreta from the bowels of infected persons to find lodgment on the soil, and then hatch into infective larvae ready to carry the disease to some other human being or reinforce the infection of the original victims.

There is no other disease perhaps which is so well understood in every detail, and which can be so satisfactorily explained to a layman. Nor is there any other widely prevalent disease against which the lay community can so readily and surely protect itself by simple precautions. Its conquest virtually resolves itself into a problem of education against soil pollution.

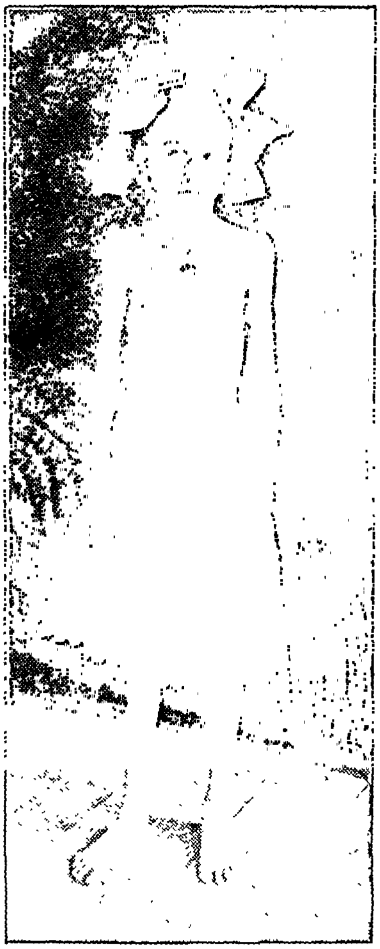

Fig. 2.—D. C. of Grant County, Ark., aged 16, practically an invalid from childhood, has been treated for malaria and tuberculosis. She was found heavily infected with hookworms and was given treatment.

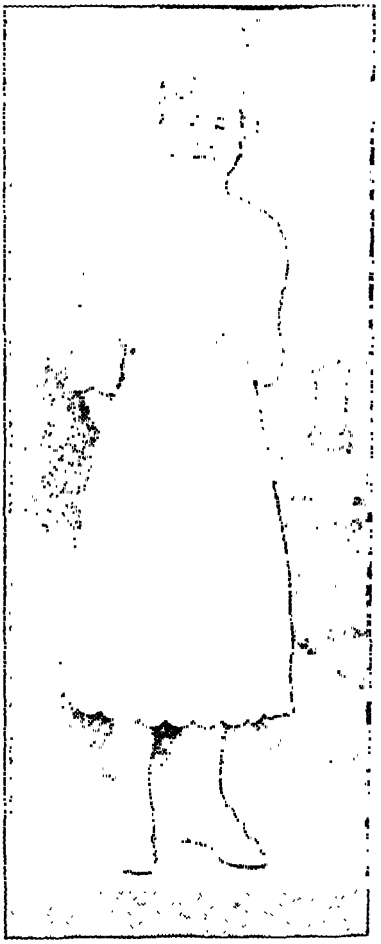

Fig. 3.—D. C. as she is to-day.

The largest possible public therefore should be brought to know in detail the history of hookworm disease; the distribution and life cycle of the parasite causing it; its symptoms, method of cure, and, most important of all, means of absolute prevention.

HOW HOOKWORM DISEASE WAS FOUND

Hookworm disease is not new. It is only newly understood. The symptoms of the disease were described in the records of the Egyptian Empire, but its cause was not known. The hookworm itself was discovered in 1838 by Dr. Angelo Dubini, an Italian.

who while making a necropsy found the small white worm with its head buried in the membrane of the small intestine; but that this worm had anything to do with anemia was not suggested. When, however, in 1877, Grassi, another Italian physician, identified the eggs of this worm in the feces of anemic patients, it was suspected that the parasite was the cause of the disease. About the same time, Dr. Colomiatti, studying an obscure disease which had caused the death of many workmen on the St. Gothard Tunnel, discovered in the intestine of one of the tunnel victims more than fifteen hundred hookworms. This parasite, known as the Old World hookworm and named *Ankylostoma duodenale,* was carefully studied, its responsibility for certain types of anemia in Southern Europe demonstrated, and successful treatment for the disease developed.

The prevalence of hookworm disease in the New World was not recognized till much later. Nov. 24, 1899, Major Bailey K. Ashford of the United States Army Medical Corps, while treating anemia supposedly due to starvation caused by the hurricane in Porto Rico, identified the hookworm as the real cause of the wide-spread disease. He, however, supposed the parasite found by him to be the Old World type. In 1902 Dr. C. W. Stiles of the United States Public Health Service, having found the same disease in the Southern States, identified its cause as a different species of worm, now known as the New World type, or *Necator americanus.* It was then discovered that the worm found in Porto Rico was of this species.

Subsequent discovery of the same worm as the cause of anemia among the victims of the African lowlands suggests that the so-called New World type was brought to Porto Rico and the Southern states by the slave trade. This form also prevails in India, and has been carried to Jamaica, Trinidad and British Guiana by the Hindoo coolies brought there as laborers. The disease caused by one or the other of the two types of hookworm is now known in practically all tropical or semitropical countries, but all the worms look alike to everybody except the expert zoologists; they produce practically the same symptoms; substantially the same treatment is effective with all, and they can all be prevented by the same means.

HOW THE HOOKWORM LIVES AND WORKS

The hookworm in adult life is a small, round intestinal parasite about ⅓ inch in length, and about the size of No. 30 sewing thread. As a type it is found to infect man and numerous animals, such as the dog, the fox and the cow; but the particular species infecting man have not been found in animals, nor those of the lower animals in man. Only the type infecting man will be discussed here.

The life of the hookworm is made up of two periods. During the first period the worms are microscopic in size and live in the soil. It is in the soil that they hatch from microscopic eggs (Fig. 4) which were deposited there with the excrement from some person having hookworm disease. Neither the eggs nor the larval worms hatching from the eggs can be seen with the unaided eye. These minute worms will live for perhaps ten or twelve months under favorable conditions of warmth and moisture; but they cannot develop beyond this point unless they gain entrance into the body of some human being and find their way into the intestinal canal, usually the upper portion of the small intestine. The drying heat of the sun and the freezing weather of winter are destructive both of the development of the hookworm eggs and to the life of the larvae. For this reason the disease is rare in deserts and in countries having protracted cold weather. A porous, sandy loam soil, having reasonable shade, affords the most favored habitat for the hookworm larvae. Though in stiff clay soil conditions are much less favorable to these little worms, we often find that enough of them have lived and entered into the second period of their life's existence to cause heavy infection.

The second period of the hookworm's life is spent within the body of a human being. The great majority of the worms never reach this stage in their development. In fact, many of the eggs never hatch. Yet when we stop to consider that in some localities 90 per cent. of the people are severely infected, and that each infected person will daily cast off with the excreta from one to four million eggs on the soil, we can appreciate that even with this loss it will be almost impossible for one to escape infection in a section where wastes from the human body are not properly disposed of.

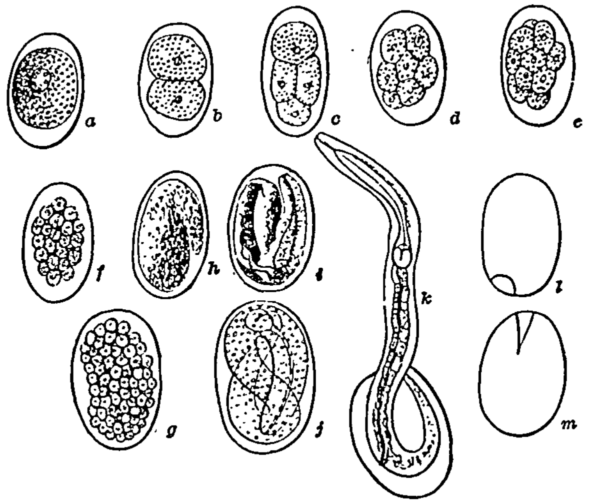

Fig. 4.—Development of Old-World hookworm: *a-g,* changes occuring in egg preparatory to developing of little worm; *h-k,* stages of the worm's development until it emerges from the egg-shell; *l, m,* empty egg-shells; greatly enlarged. (After Peroncito. Courtesy of C. V. Mosby Publishing Company.)

With these facts before us we at once want to know how these invisible filth-borne pests find their way to our small intestines. The answer may be a short story, but generally it is a long one.

It may be short because the little worms may cling to food which is swallowed by the unsuspecting victim. They may be carried on soiled hands; or, perhaps more frequently, may be swallowed along with uncooked foods, such as strawberries, plums, celery and lettuce, grown in or left to lie on ground polluted by human excreta.

Though some infection is thus taken through the mouth, the most of it is acquired through the skin in a very interesting way. In brief, this is the story of the hookworm's most common progress: Within a week of the hatching of the larvae they molt and shed their skin twice. They are protected by the second sheat, and are very tough. In this stage they possess the wonderful ability to burrow (Fig. 5) in a few minutes through the skin and to enter the tiny blood capillaries, where, carried along by the blood-current, they make a long journey through the body to the heart and to the lungs. In the lungs the blood-vessels are too small to permit them to pass through, so they begin to burrow again, and soon find themselves in the air-spaces of the lungs. Crawling along these they reach the wind-pipe and then the throat. Once there the worms are swallowed with saliva and food, and thus by this long journey find their way to the intestine, where they fasten on its walls and begin their blood-sucking.

One would think that the hookworms would have great difficulty in penetrating the skin and the blood-vessels in the lung, yet they do it. The fact can be easily demonstrated by experiment. If the polluted soil in which the larvae are known to be is moistened and applied to the skin, the point at which they enter will become inflamed and an eruption will appear, which is commonly known to the barefoot boys and girls as "ground-itch." Moreover, by the end of eight weeks, examination and treatment will show the person to be harboring adult hookworms, even though it may have been demonstrated that he was not infected up to the time he was brought in contact with the polluted soil. It should be remembered that the presence of "ground-itch" or "dew-itch," even though the skin may heal quickly, usually means that hookworms have entered the body and are beginning to rob the victim of his blood and vitality.

The second period in the life history of the hookworms begins with their entrance into the intestinal canal. There the male and female worms, after molting twice again, develop to adult life. From five to eight weeks is usually required for their growth. When grown they may usually be seen with the unaided eye. At this stage they fasten on the wall of the intestine, live for many years, and do the harm to be described next. Besides this the females deposit thousands of eggs, which, being mixed with the excreta, pass out on the ground to spread the disease.

Now that we have followed the complete life cycle of the parasites, let us study the disease caused by the adult worm in the intestine.

THE EFFECTS OF HOOKWORM DISEASE

When we consider that several hundred hookworms may live in the intestine at one time, and that they may live there for from six to ten years—sapping the blood, wounding the intestine, and poisoning the body—it is not strange that the body becomes diseased. The blood is needed to collect oxygen in the lungs and the food from the intestine, and distribute them over the body. In the disease much blood is lost. Some of it is taken into the bodies of the worms, and a great deal more is lost by bleeding from the small wounds made by the worms. In severe cases of the disease, the blood is reduced to one-fourth or one-sixth of what it should be. In such cases we find the victim's normal color replaced by a pale, sallow complexion; the lips are pale; the mucous surfaces generally are pale, and the skin is of a pale, yellowish hue. The eyes are listless, the pupils dilated and not very responsive to light; often they present a blank stare, fish-like in character. The hair is dry and scant, especially in the armpits. The face and the ankles are often swollen, anemic ulcers frequently appear on the legs, and the abdomen is prominent, giving rise to the term "pot-belly." The chest is flat, and the shoulder blades stand out prominently, suggesting "angel wings." When the disease occurs during the growing period there is a marked retardation in development; that is to say, a boy or girl may not be developed at 18 beyond what would be expected of one at 13 or 14 years of age. The appetite is often perverted, so that the sufferer has a craving for a particular kind of food, and often for certain substances not foods. For example, victims of the disease frequently crave clay, and for this reason are termed "dirt-eaters." Again, coffee-grounds or salt may be the substance desired.

The intestinal wall is considerably damaged by the worms, and becomes tender to pressure over the pit of the stomach. Where the worms bite, raw surfaces are left, so that it is easy for any germs, such as may cause typhoid fever or tuberculosis, to get into the body and set up a disease more violent in character, and more frequently fatal, than hookworm disease. There may be severe headaches, lassitude, dizziness and inability to sleep. The heart is poorly nourished by the impoverished blood, yet it is called on to do the work necessary to keep the body supplied with oxygen from the lungs and food from the digestive tract. As a result, the heart's action becomes labored, so that hookworm disease is frequently mistaken for heart-disease or Bright's disease. Most of these cases can easily be cured by getting rid of hookworms.

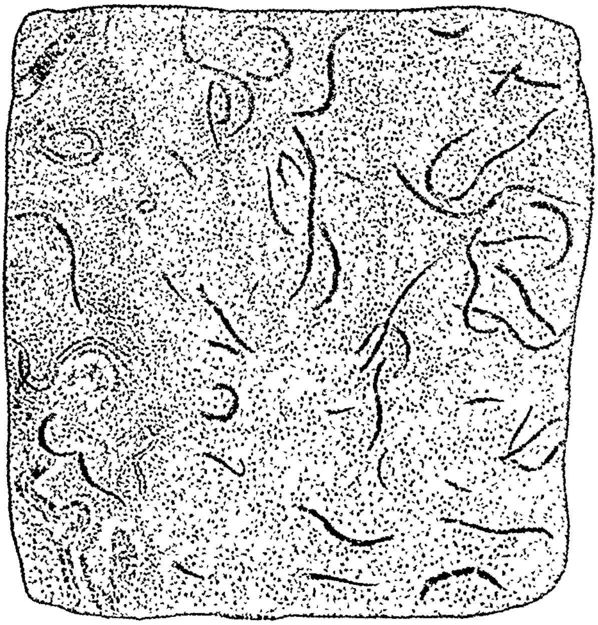

Fig. 5.—Slice of skin as seen under the microscope. Note how the younger hookworms are crawling through the skin. This is how "ground-itch" or "dew-itch" looks. (U. S. P. H. Service.)

It must not be inferred that every person who is infected with hookworms suffers with all the symptoms mentioned. Much of the infection is so mild that the presence of the disease might not be suspected. In cases of medium severity one or more of the symptoms will be present, but the existence of the disease cannot be confirmed until the eggs of the worms are demonstrated in the excreta by microscopic examination.

The disease, however, even in very mild cases, is a menace for two reasons: First, any infection exerts a handicapping influence on the victim. This has been shown among students who, though mildly infected, were underdeveloped in size and were backward in their studies; and, being below the standard, they were more subject to other diseases. Second, the persons mildly infected are carriers and distributors of the hookworm eggs, and may become responsible for the disease in a severer form in themselves and in other persons.

HOW HOOKWORM DISEASE SPREADS

We have seen how each of the female hookworms living in the intestines deposits hundreds—often from twelve to fifteen hundred—of eggs daily; that these eggs do not hatch while they remain in the bowel, but after they have passed out on the soil, where there is moisture and warmth—but not too much—they hatch into larvae. Both the eggs and larvae are too small to be seen with the naked eye. The larvae remain invisible in size unless they can get into the intestine, which they may reach by being swallowed with food or by entering the skin, usually of the feet, there producing "ground-itch" or "dew-itch," and then making a long journey through the body until the intestine is reached.

When infected persons go from place to place they spread the infection. It is thought that the negro slaves brought the disease to America from the West Coast of Africa. Likewise, the disease may be carried from one community to another. Suppose we have a school district at A where there is no infection, and the people are healthy and thrifty; and from this community the son and daughter of Mr. Jones visit the Smiths in the distant community of B, where 75 per cent. of the residents have hookworm disease, and the soil is teeming with the larvae; that is to say, there is heavy soil pollution. Neither the Smith nor the Jones family pays much attention to the use of privies; indeed, there is much doubt if either has one; for out of 189,586 rural homes in the Southern states inspected by the Rockefeller Sanitary Commission, 95,988 were found to have no privies at all and 87,156 to have open privies which allowed wastes to spread freely through the soil. The sun is warm, and the Jones children go barefooted and contract "ground-itch." They eat strawberries and plums which have been on the ground. By the time their visit is over they have become infected with grown hookworms. Returning, they begin to pollute the soil at their home. The other members of the Jones family get the infection, and by the end of the summer they are all becoming pale and puny. The district school at A opens. The Jones children, though not in their usual health, go to school. The school has been equipped with many of the modern conveniences, but has not been provided with privies. The need of them was not really felt. The boys concealed themselves in woods and undergrowth to the east, and the girls to the west of the schoolhouse. The Jones children, not knowing they have a disease, of course, do not know they are spreading one when they use the common hiding-grounds. In ignorance of the disease and in ignorance of sanitation, which the school should be teaching in a practical way, the soil around the school becomes heavily polluted, and a center for spreading the disease from one family to another. Soon the community has hookworm disease. Sometimes every pupil in a school gets it. The people become sick, backward, lazy, poverty-stricken and "trifling"; no one seems to suspect when, how or why "hard times" overtook the community. Had there been sanitary privies in use by all the people of the district, the disease would have been limited to the two Jones children, and their infection would have been mild. This is so, because when the hookworm eggs are collected in a sanitary privy they never reach the soil where, by hatching into larvae, they can do the harm.

HOW THE DISEASE IS RECOGNIZED

Hookworm disease is recognized with certainty in two ways. If it is suspected from the clinical symptoms already described, the treatment, which is very simple and inexpensive, may be given. If the disease exists, the worms which cause it will be poisoned and dislodged by the medicine, and may be found in the stools. By washing the stools through one or two thicknesses of cheese-cloth, the worms will be left on the cloth, and may be seen and collected with ease.

The second method is the one commonly employed. Nearly a million persons have been examined in eleven Southern states by its use during the last four years. A small portion of the bowel movement is spread out thinly in water on a glass slide, and placed under a microscope. If the hookworm eggs, which are very characteristic in shape and size, are found, it is known that the hookworms are in the bowel, and that treatment for their removal should be taken. Hundreds of the best people, men, women and children in the South, are seeking examination by this method, and are putting aside all squeamishness in the determination to rid themselves and their communities of this pest.

HOW HOOKWORM DISEASE IS PREVENTED

There are two ways to get rid of hookworm disease: one is to prevent it, the other to cure it. Unfortunately as a people we are slow to apply preventive measures against disease. This means that we have too much disease, and, of course, that we rely too much on treatment. Preventive measures against hookworm disease are very simple. All that is necessary is to have the excreta of every person collected and disposed of in a way which will keep the hookworm egg from developing. If this should be done in every case, the hookworms, not multiplying in the intestine, would die in a few years of old age and the disease would become extinct.

Until this can be accomplished much infection can be prevented by wearing shoes. The barefoot boy is a great gatherer of hookworms. But the really effective protection from the disease is to be found in clean soil. That can be secured when sanitary privies are constructed and regularly used by all the people. Even if those persons now infected should refuse treatment, but could be induced or required to use sanitary privies, the country would in a few years be freed from the disease.

The common pollution of the ground about schools and farmyards must be stopped. The tumble-down shack and surface privy which allow their contents to be spread over the soil, by rains, hogs and chickens, or carried by flies to the houses, must be abolished, and replaced everywhere by the sanitary privy, the essentials of which are that it have a water-tight, fly-screened receptacle, and that the contents be disposed of in a sanitary way, by burning, fermenting, or burying away from and below the water-supply. Human excrement should not be used as a fertilizer unless thoroughly treated under competent direction; otherwise it may carry hookworms to fruit and vegetables.

An inexpensive privy which can be easily provided for the most simple farm or cottage has water-tight pails, tightly closed in, close-fitted door, and all openings covered with wire mesh to exclude flies.

Many communities are already putting in such privies, and there is a growing movement for placing them in every rural schoolyard of the South as a protection against hookworm, typhoid and other diseases.

All plans for privies approaching the ideal thus far presented seem to be too expensive or otherwise unpractical. The feeling is growing that some practical arrangement should be recommended, even though from the point of view of the idealist it is not without danger. We know that trains, automobiles and elevators are dangerous to a degree, yet no one would be so foolish as to advise that we avoid the use of these conveniences of civilization until the element of danger is absolutely eliminated. Working on this principle, sanitarians are now recommending as a minimum for a privy, first that a hole be dug in the ground; second, that a substantial box with a hole in the bottom be turned upside down over the hole in the ground and dirt banked around the lower edge of the box; third, that the hole in the box be covered when not in use; fourth, that the box be moved from time to time and the pit filled up with dirt. This privy may be built out in the bushes or it may be within expensively constructed walls. For all practical purposes an arrangement of this kind will eliminate hookworm eggs as á source of danger, and so long as it is fly-proof it will guard against the spread of typhoid fever by flies. If located a reasonable distance from the spring, or well, and below it, the danger of pollution is negligible, except perhaps in certain areas where the formation is largely limestone.

Fig. 6.—Tennessee family, all infected. All were cured with thymol. They had spent $1,500 for patent medicines.

HOW HOOKWORM DISEASE IS CURED

Hookworm disease is usually treated with Epsom salts, and with powdered thymol given in capsules. The object of the Epsom salts is to free the intestine from mucus or other substances surrounding the hookworms and protecting them from the action of the thymol. The patient should take little or no supper on the evening before the thymol is to be administered. As early at night as is convenient he should take a dose of Epsom salt. The next morning as early as the salt has acted, half the number of capsules of thymol prescribed for the whole treatment should be taken. Two hours later the remaining capsules should be taken. Two hours after the second dose of thymol, another dose of Epsom salt should be taken, which will expel the hookworms that have been forced to loosen their hold on the intestinal wall by the action of the thymol, and will also get rid of the excess of thymol before it has had time to produce any harmful effects on the patient. Nothing should be eaten on the day the capsules are taken until the final dose of Epsom salt has acted well. A little water or strong coffee, *without* milk, should alone be allowed.

As alcohol and oils dissolve thymol, making it actively poisonous to the patient, the use of them in any form would be exceedingly dangerous. Gravy, butter, milk, all alcoholic drinks and patent medicines, which generally contain alcohol, should be forbidden on the evening before and on the day of the treatment. Moreover, as many hookworm patients have dilated stomachs which do not readily empty themselves and it is important that the thymol reach the small intestine at once, the patient should lie on the right side for at least half an hour after taking each dose of thymol.

DOSE OF THYMOL

Age, Years	Grains	Grams	6 a. m.	8 a. m.
1 to 5	7.5	.5	½ dose	½ dose
5 to 10	15.	1.	½ dose	½ dose
10 to 15	30.	2.	½ dose	½ dose
15 to 20	45.	3.	½ dose	½ dose
20 to 60	60.	4.	½ dose	½ dose
60 and upward	45.	3.	½ dose	½ dose

The dose of thymol varies with the age of the patient. As the disease retards development and persons 18 years old often have only the normal growth of 13, apparent and not actual age determines the dose. A competent physician, of course, should supervise the treatment. The accepted scale of doses is shown by the accompanying table.

The thymol is powdered and given in capsules. If sugar of milk is added grain for grain, the thymol operates better.

In a majority of cases two treatments like the one just described will expel all the worms. In 1,518 out of 3,630 patients treated in Porto Rico, a single treatment effected a cure; a second treatment was sufficient in 1,166 cases; 518 required a third; 247 a fourth; 104 a fifth; 47 a sixth, and so on until the last case was freed from hookworms by the eleventh treatment. Frequently the worms not killed by the thymol are sickened to a degree that they do not deposit any eggs for approximately two weeks. By a microscopic examination, made two weeks or longer after the last treatment, it is possible to know when all of the worms are destroyed, and the treatment completed. When a microscopic examination is not possible, the feces expelled by each treatment can be examined for hookworms in the manner already described. When no more worms are seen, one extra treatment for good measure should be given.

INDUCED PNEUMOTHORAX *

EDWARD VON ADELUNG, M.S., M.D.
OAKLAND, CAL.

The rational basis of induced pneumothorax as a treatment for certain pulmonary diseases is the fact that clinicians have noted for many years that consumptives are often relieved and sometimes cured by the spontaneous occurrence of hydrothorax or pneumothorax. Such observations have been recorded to a considerable number, both by old and by modern observers, including Bach, Goodhart, Hall, Jochman, Pepper, Webber, West, Osler, Hamman and Sloan. The presence of even pus in the pleura — empyema — is no longer considered *per se* an indication for surgical interference. Indeed, Murphy and other surgeons counsel delay in such cases until the underlying disease of the lung has had an opportunity to profit by the rest incident to its collapse. I myself have noted the excellent results that follow delayed operation in empyema complicating tuberculosis of the lungs. In the treatment of joint tuberculosis nothing is regarded as more essential than rest; indeed, in many cases fixation alone is sufficient to procure healing. The value of rest is not a whit less important in pulmonary tuberculosis. Once this principle has been grasped, the treatment of pulmonary tuberculosis by securing organ rest through mechanical measures appears quite rational. It remains only to determine by which mechanical means this object shall be obtained.

Various mechanical methods have been devised. Several styles of roller bandages, usually designed to compress one-half of the thorax by using the opposite shoulder for counterpressure, have been offered, but have never gained wide acceptance. Adhesive straps have also been employed and are to-day the accepted method of fixation of the chest wall in fractures of the ribs and in acute pleurisy. Plaster casts, cumbersome as they are, have been fashioned, and even a curious spring clip similar in conception to the ordinary paper clip, has been tentatively offered by an Englishman, to restrict movement of half the thorax. These methods are all open to both theoretical and practical objections, and therefore have gained but little recognition. Such tinkering devices were soon cast aside as inadequate in the presence of so serious a disease as consumption, and attention was concentrated on massive surgical operations. Suffice it here to say that they are not generally resorted to as efficient cures for pulmonary tuberculosis. Their object has been either the removal of diseased tissue, a task surrounded by unusual difficulties, or fixation of the lung.

More recently attention has been directed to fixation of the lung by another method — the introduction of gases or fluids into the pleural space. On account of the well-known physical law that gases exert their pressure in all directions equally, gases have been employed almost to the exclusion of fluids.

HISTORY OF THE PROCEDURE

The first record of such a procedure is attributed to James Carson, an English physiologist, who in 1821, while experimenting on lung elasticity, inflated the pleural sac of animals and foretold the value of induced pneumothorax in the treatment of pulmonary diseases, especially tuberculosis, but did not apply it clinically. In 1882, Forlanini of Pavia, Italy, reported a number of spontaneous cures by intercurrent pneumothorax, and advised that pneumothorax be induced artificially. In 1887, Adams reported a case of hemoptysis controlled by spontaneous pneumothorax, and advised its artificial induction. In 1892, Forlanini actually began to employ artificial pneumothorax; he made his first report in 1894. By 1895 he was able to offer a cure of well-advanced pulmonary tuberculosis by this method. Meanwhile, and without knowledge of Forlanini's work, Murphy of Chicago devised and applied the same treatment in five cases, in all of which he reported improvement in 1898. In the same year Schell reported a case of hemoptysis controlled by induced pneumothorax. Murphy, being a surgeon, and not desiring to be led into the field of internal medicine, turned his work over to Lempke, who reported fifty-three cases in 1889. About seven years ago Brauer made his first report, and since then has added much to the literature.

Since the publications referred to above, a number of tuberculosis workers on the Continent, in England, and more recently in America, have adopted the procedure. The principal credit of demonstrating the value of induced pneumothorax belongs to Murphy and Forlanini, although Brauer's work did more to popularize the method.

APPARATUS

While various forms of apparatus have been devised for introducing gas into the pleura, the simplest, and I think the best, are modeled after Murphy's original form. I shall therefore present such an apparatus, which is the form I have constantly used. Figure 1 represents two graduated bottles *W* and *N*, connected by tubing so that water flows from the upper to the lower, displacing gas from the latter, and forcing it through the tubing and needle into the pleural sac. The accessories are a cotton filter, *F*, for the gas, and a manometer, *M*, for recording intrathoracic pressures. A three-way stopcock, *C*, permits one to connect the patient at will with the manometer or with the gas container, *N*. In the tube leading from *C* to the manometer, is inserted the capillary device, or link, for controlling oscillations.

---

* Read before the meeting of the California State Medical Association, April 15, 1914.

GAS

Various gases have been tested out. Unverricht found experimentally that when air is injected into a dog, the oxygen content is absorbed first, then the carbon dioxid and last the nitrogen. Not only is nitrogen slowly absorbed, but it is also inert and nonirritating, and therefore well suited to pneumothorax. My work has all been done with nitrogen, sterilized by being passed through red-hot tubes, washed and warmed immediately before use by being placed in a container which has been filled with hot mercuric chlorid solution, and filtered through cotton just before passing through the needle.

NEEDLES

In many cases some difficulty is met in getting the eye of the needle into the pleural sac, which before inflation is of course not a cavity, because the two pleurae cling together both by virtue of the vacuum in the sac, and by capillary attraction. The adhesion is such that even when the parietal pleura is cut, the lung does not immediately collapse. The layers still cling together even in the presence of atmospheric pressure. It is readily understood, therefore, that a dull instrument is more serviceable for finding the sac, as it is more likely to push the visceral pleura before it than to penetrate into the lung.

Manual dexterity and experience are here of great value. The experienced hand judges by the feeling what tissue the needle is penetrating. An educated tactile sense distinguishes with considerable certainty the feeling due to passage through the fascia, the resistance of the pleura and the feeling when the needle is embedded in the lung.

After the sac has once been inflated, subsequent punctures are easily made with a sharp needle, provided the gas has not been absorbed. It is injection of the empty sac that is difficult. A form of dull needle that has been serviceable in my hands is the Bauer needle modified by Floyd (*B*, Fig. 1). It has the advantages of an attached obturator for clearing the lumen, and a separate branch for the tube leading to the controller. Although the dull needle has its advantages, experience makes it easy to find the sac with a sharp needle. In my inflations, numbering over 614, I have used a sharp needle far oftener, even for first inflations.

MANOMETER

The heart of the apparatus is the manometer. When properly observed and followed, the readings of this instrument render the operation safe from accident. It serves two main purposes: when the needle has been introduced properly so that its lumen lies in the sac, the manometer announces the fact by free oscillations and a sustained negative pressure. To proceed without this information is to invite disaster. The second purpose served by the manometer is to indicate intrathoracic pressures, thus serving as the indicator and guide during the operation.

The manometer (*M*, Fig. 1) consists simply of a glass U-tube graduated in centimeters and filled with a fluid, usually water. Thoracic pressures are transmitted through the tube *X* (Fig. 1), and depress or suck up the fluid according to whether the pressure is positive or negative. Inasmuch as the patient continues to breathe, the pressure varies constantly, and therefore the columns of fluid are in constant oscillation. Inasmuch as not all operators are reading the manometer the same way, it may not be amiss to refer to this point.[1] Physics made clear long ago that pressure is measured by the column of fluid supported. Now the column supported is that portion of the longer column above the shorter. But as the columns are oscillating, one may record the maximum length of the column or its minimum length. But what is better than either, because it varies less, is the mean pressure. To secure uniformity and simplicity, it is here suggested that mean pressures be the figures recorded.

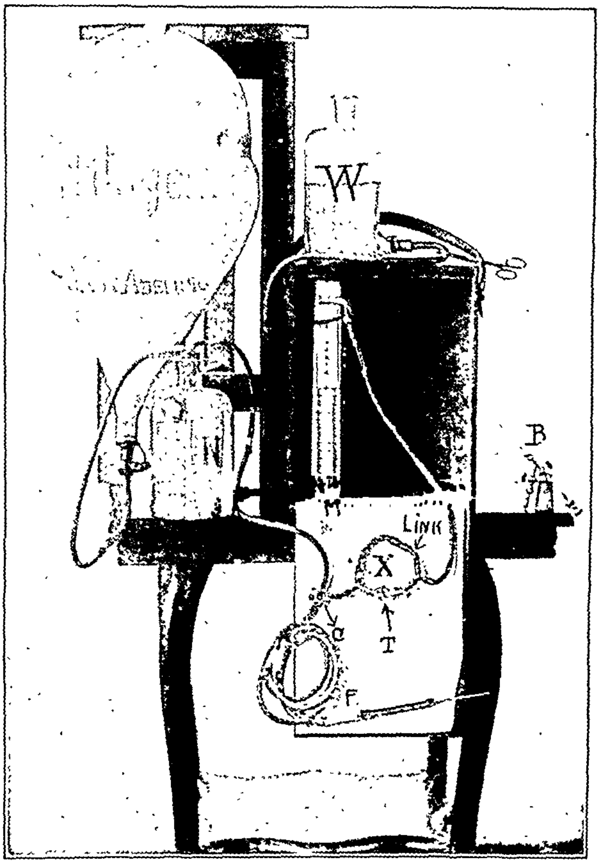

Fig. 1.—Portable apparatus; *W*, water-bottle; *N*, nitrogen bottle; *M*, Manometer; *c*, three-way stop-cock; *F*, filter; *B*, Floyd needle; *X*, tube leading from *c* to *M*, divided into two portions, on one of which is inserted the "link," the other branch furnished with a pinch-cock, *T*. The whole apparatus except the bag of gas is carried in the small box.

Fortunately, by employing a simple attachment,[2] shown in Figure 2, mean pressures can be read directly, that is, free from oscillations. Thus a positive-reading manometer for mean pressures is readily available. The attachment consists of a capillary tube fixed in a larger tube (for protection) or any similar device that forces registration through a minute opening, *C*. This device is placed in one limb of the divided tube leading to the manometer (Fig. 1). When the rubber tube, *T*, is pinched off, forcing all pressures to reach the manometer through the link, mean pressures will be recorded with no oscillations. But, as all workers know, the oscillations are necessary for several purposes, and are indispensable to prove the position of the needle — to show when it is in the pleural sac. If the tube, *T*, is left open, oscillations occur as usual. Thus both uses of the manometer are readily available.

[2] Von Adelung, Edward: The Pneumothorax Manometer, THE JOURNAL A. M. A., Sept. 6, 1913, p. 771.

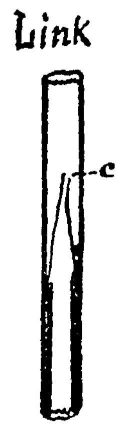

Fig. 2. — Capillary opening in small tube sealed into larger tube.

The advantages of this link are (1) ease of reading; (2) uniformity of records; (3) protection of manometer against overflow when patients cough, and (4) greater accuracy, inasmuch as the mean pressure varies less than either maximum or minimum, namely, than either the expiratory or inspiratory pressures.

When the language of the manometer has been mastered the following information is available from its readings:[3]

1. When the needle is in the pleural space, a negative mean pressure with free oscillations is recorded.
2. When the needle is in the air-space of the lung, free oscillations occur that are equally above and below the zero point.
3. It indicates the size of the pleural space; a free pleura requires many hundred cubic centimeters of gas before the pressure becomes positive. If a few hundred cubic centimeters of gas produce a positive pressure, it indicates a small pleural space.
4. If the needle is embedded in adhesions or if it is extrapleural, no oscillations will occur.
5. The readings indicate the absorptive power of the pleura by the amount of gas that must be injected to regain the terminal pressure of the previous inflation.
6. It indicates the degree of elasticity of the compressed lung: during subsequent filling, if the pressure rises very gradually on introducing 100 c.c. at a time it indicates that the lung had expanded with the diminished pleural pressure. Had the lung remained collapsed, there would have been but slight rise of pressure until after considerable gas had been refilled.
7. A slow increase in pressure with wide oscillations indicates an elastic mediastinum, while the reverse indicates a rigid mediastinum.
8. Rarely, the rupture of adhesions during inflation is indicated by sudden fall of pressure, or still more rarely, rupture of the lung or of the mediastinum.
9. Occasionally, reversed oscillations occur—that is, a higher pressure with inspiration than with expiration. This is due to paradoxical diaphragm movements.
10. If, when the patient takes a deep breath or coughs, the column is moved several degrees but fails to oscillate, it is an almost certain sign that the apparatus is obstructed — usually in the needle.

TECHNIC

As far as the operation is concerned, the main difficulty is the entry of the empty pleural sac, which is frequently obliterated by adhesive pleurisy. And even if it is patent and normal, it is a mere line between two serous layers in apposition. Two procedures are recognized: (1) the Brauer, or open method, which consists of exposing the parietal pleura by incision, and dissection, and the introduction of a catheter between the two pleurae, under guidance of the operator's eye, and (2) the Forlanini method, or blind operation, which consists simply of passing a hollow needle through the chest wall into the pleural sac, the operator being guided by the sense of touch and the manometer.

American operators prefer the Forlanini method. I have not used the Brauer incision, though I have no doubt that it might succeed when the puncture method fails. The objections to it are that it consumes time and requires incision, dissection, suturing, careful asepsis and dressings. Furthermore, it is more likely than is the blind method to be followed by subcutaneous emphysema. Finally, more patients object to cutting than to the needle.

In contrast, Forlanini's puncture is simple, safe in careful hands and successful in nearly an equal number of cases. If an adherent pleura is encountered, subsequent attempts in new sites means simply painless needle-punctures instead of incision operations. No dressing is needed after the puncture, and less fear is engendered than by the knife.

AUTHOR'S TECHNIC

Information gained from roentgenoscopy, from physical signs and from the patient's statement which side was first affected, guides me in selecting the worse side for operation. The patient usually lies down. The exact site is chosen by finding a place that is resonant, yields breath-sounds and is away from important organs. It is impossible, however, to foretell the presence of adhesions. The chosen spot is sterilized with tincture of iodin, and then a few drops of novocain in epinephrin are slowly injected, first intracutaneously, then subcutaneously, intramuscularly and finally into the pleura. If the dull needle is to be used, the skin is first punctured with a sharp instrument. If the pleura already contains gas, a sharp, short aspirating needle, with obturator, is pushed directly into the pleural sac. If, however, it is a first injection, I use either a Floyd needle, or preferably the sharp needle, pushing it very slowly through the skin, muscles, fascia and finally through the parietal pleura, judging of its location largely by tactile sense, but always depending on the manometer. When the manometer records a negative mean pressure with free

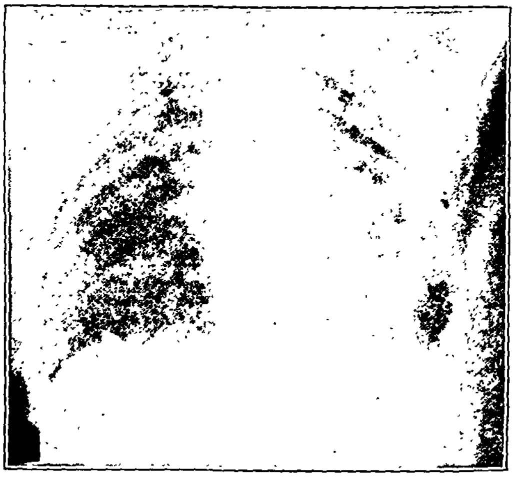

Fig. 3.—Case 553, W. Before treatment.

[3] Adapted from Hamman and Sloan: Johns Hopkins Hosp. Bull., 1913, xxiv, No. 264.

oscillations I know that the needle is properly placed. After noting the initial mean pressure, I inject gas slowly to a variable amount, usually not more than 200 or 300 c.c.

The terminal mean pressure is then recorded and the needle withdrawn. Should it happen that too much gas is introduced, the removal of the surplus is a very simple matter, requiring only that one reverse the position of the bottles (*W* and *N*, Fig. 1). No dressing is applied. As soon as the needle has been properly placed, the manometer becomes the guide and is consulted frequently during the introduction of the gas. Injections are repeated as frequently as needed, depending on the rapidity of absorption, every two or three days up to once a month, the object being to maintain collapse of the lung. At first the intrapleural negative pressure, usually from 2 to 10 cm. water, is reduced to 3 or 5 cm. negative mean pressure. Only after several treatments is a neutral or a positive pressure produced, thus allowing time for thoracic organs to accommodate themselves to the new pressure and to their inevitable displacement, and to allow the other lung to prepare to compensate.

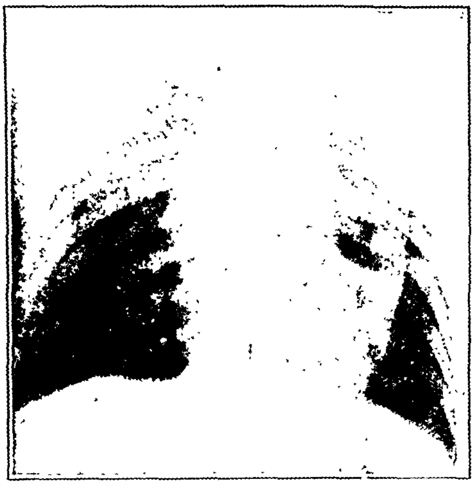

Fig. 4.—Case 517, W. Adhesions allow only small pneumothorax, yet good results followed.

When a positive mean pressure has been attained, I take the second roentgenogram as a record, to indicate the size and shape of the pneumothorax. Other roentgenograms are taken when needed for information. The lung is kept collapsed for many months — a year, or even longer in some cases. Brauer fixes the period at from one to two years, but says that he has seen good results in six months. Improvement, however, not infrequently sets in shortly after the beginning of treatment. When the treatment is discontinued, the lung usually expands and functionates again as well as the fibrosis of the healed parts can be expected to allow.

In some bilateral cases, after compressing one side for several months, I have allowed the lung to reexpand, and have then treated the opposite lung in the same way. Recently, in a few desperate cases of bilateral infection, I have done a partial inflation of the two sides *simultaneously*, the result thus far being apparently beneficial.

PATHOLOGY

The pathologic changes found after continued compression of the lung indicate the value of the procedure. According to Forlanini, Saugman, Graetz, Warnecke and Kistler, the most striking changes resulting from compression are the following: There is marked fibrous formation and no evidence of advancing disease; old caseous areas are surrounded by dense fibrous tissue; the alveolar epithelium is transformed into the cuboidal or columnar type; the lymphatics are dilated and richly pigmented, a condition indicating marked stasis in the lymphatics; the circulation of blood is likewise altered. In spite of long-standing atelectasis, the alveolar walls, though pressed together, do not adhere. That the process in the other lung may also be arrested, although doing the work of two, is vouched for by nearly all observers — Hamman and Floyd, Brauer, Spengler, Forlanini and many others.

The immediate results of pneumothorax are often unfavorable: the cough increases, the sputum augments, the toxemia increases as evidenced by rise in temperature and pulse, dyspnea grows worse, and the patient loses in weight and appetite. After a few weeks, however, the benefits become apparent. The collapse of the lung has secured physiologic rest, and the walls of cavities are approximated, thus aiding their healing and abolishing hemorrhages. The lung contents — air, pus, secretions and detritus, with their rich bacterial flora — are mechanically expelled, reducing or abolishing cough and sputum; the lymphatics and blood-vessels are compressed, inhibiting the spread of the infective germs and of their toxins, often rendering the sputum clear of tubercle bacilli and elastic fibers, reducing or abolishing fever and sweats, and permitting the appetite to return, the weight to increase, the pulse to drop to normal, cyanosis to disappear and the opsonic index to rise. The opposite lung enlarges to compensate for the defunctionated lung area, and in favorable cases general clinical improvement follows, as expressed by a sense of well-being, and increased weight, strength and energy.

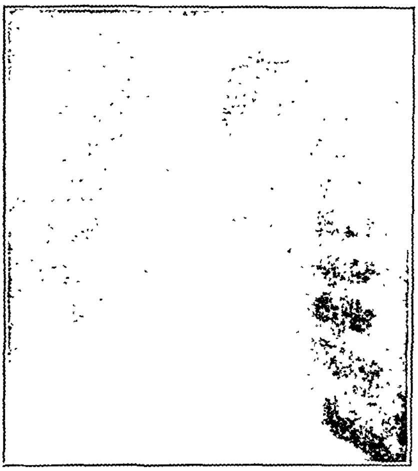

Fig. 5.—Case 523, Ch. Incomplete left pneumothorax; large cavity; diaphragm adhesion; fibrosed upper lung; result excellent.

ACCIDENTS

I have now to refer to some accidents that may befall in artificial pneumothorax, and to indicate how they are to be avoided. Pain from the needle can be entirely avoided by careful local anesthesia as previously described; but pain occurring during or after an injection, probably because of tension on pleuritic adhesions or to displacement of organs, is often unavoidable. It is rarely of long duration, and is best minimized by gradual attainment of the desired pressure.

Subcutaneous emphysema results from inducing considerable positive pressure, or from coughing, straining, etc., and is due to leakage from the pleura back through the puncture into the tissues. It is more common after the Brauer incision than after the Forlanini puncture, but will ensue after either if much positive pressure is induced. Strapping a hard pad over the puncture will often prevent the return of gas. Digital pressure continued for from ten to thirty minutes is entirely successful. A spring pad like a hernia truss is useful. When subcutaneous emphysema invades the neck and face, it becomes distressing, but is never a danger.

Bleeding from the opposite lung, in bilateral cases, due probably to compensatory stretching of the lung, is usually regarded as a rare accident. It occurred in two of my cases.

Puncture of the lung is to be avoided, though it commonly causes no difficulty. It is easily conceivable that the pleura might be infected by wounding the diseased lung, but most observers do not find that serious results follow this accident. Hamman and Sloan state that "simple puncture of the lung with an aspirating needle, even when the lung is diseased, is associated with little danger." My experience leads me to believe that lung wounds from punctures are rarely followed by more than temporary pleuritic pain, or by bloody sputum.

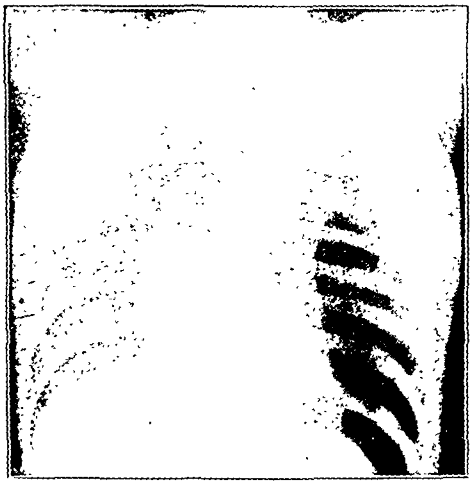

Fig. 6.—Case 508, O. Almost complete left pneumothorax; adhesions at apex, diaphragm and third rib; result excellent.

But the pleura can doubtless be infected by an unclean needle or other surgical septic error. No operator can afford to neglect strict asepsis in this operation, especially as it is stated that 50 per cent. of pneumothorax cases develop pleuritic effusion. I think this figure may be too high. In a series of forty-two cases with 614 punctures, I encountered a pleuritic effusion consequent to pneumothorax only six times. Effusions are nearly always reabsorbed after a time, and are not a hindrance to lung healing.

Displacement of the heart and aorta and mediastinum naturally occurs to some degree with inflation of one pleural sac. In most cases no distress results, but untoward symptoms have been attributed to this anatomic cause. Distress from this cause is to be avoided by inducing the complete compression gradually, so as to allow the organs time to adjust themselves to new conditions, and also by avoiding high pressures. In my experience a positive mean pressure of over 5 c.c. is likely to cause some disturbance in bilateral cases. Higher pressures are liable to cause subcutaneous emphysema and distress.

Dyspnea is liable to appear in all cases after the early inflations; it is not usually serious, and is always slight with low pressures. It is rapidly relieved by absorption of gas, and later by compensatory functioning of the opposite lung, or by adjustment of the circulatory organs. It is noteworthy that dyspnea need not follow an inflation until an hour or more later. Its appearance is frequently delayed and often manifest only during exertion. In certain unsuitable cases, or when high pressures are used, dyspnea may become an important complication. The interesting question of the least lung capacity compatible with life has been investigated by Le Play and Mantoux, who report that whereas Courmont destroyed, surgically, three quarters of the lungs of animals without death, they were able, by induced pneumothorax, to render atelectatic all but one-sixth of the lungs of a dog without killing him. The physiologic adjustment of the lungs is possible therefore within wide limits.

PLEURAL REFLEX AND GAS EMBOLISM

There now remain to be discussed two accidents, the most important of all; pleural reflex and gas embolism. All authorities mention these as the most dangerous of the accidents. Fortunately, only a few deaths have been reported. Forlanini reported 1,454 inflations with four pleural reflexes, only one of which was serious. In another series of 500 inflations there were three fatalities. Saugman reported 970 with no pleural reflexes; this he attributed to avoidance of high pressures. The distinction between the two accidents is not clear. Some authors hold that pleural reflex is nothing but air embolism. The usual post-mortem examination fails to show air in the blood-vessels, even when it is known to have entered. So Brauer resorted to an examination of the brain under water, by which expedient he demonstrated bubbles in the blood-vessels. Clinically, pleural réflex and gas embolism yield the same syndrome: fainting, pallor, convulsions and perhaps temporary or permanent paralysis (usually hemiplegia) and occasionally death. Indeed, while Forlanini regards "pleural reflex" or "pleural shock" or "pleural eclampsia" as a distinct entity, and though animal experimentation is said to confirm the possibility of such a reflex syndrome, still Sampson and Brauer attribute the syndrome to air embolism in all cases, and declare that it is entirely avoided by the open method of operating. Saugman states that gas embolism does not occur unless the amount of gas introduced into the blood exceeds 20 or 30 c.c. In over 614 injections, I have not yet had such an accident, though I have seen the syndrome in a dog. There are four principal ways to avoid this serious accident:

1. A preliminary hypodermic injection of morphin is recommended as a preventive, but is objectionable for obvious reasons.
2. The Brauer incision, which enables the operator to see where the instrument delivers the gas, is urged as a preventive.

3. Saugman and some others aspirate before turning on the gas to see whether or not the needle is in a blood-vessel.

4. It has also been recommended that one first inject saline solution or oxygen until satisfied that the needle is not in a blood-vessel. My conviction is that air embolism and real pleural reflex, such as results experimentally from the injection of irritating fluids into the sac, are both to be avoided by using warm, moist nitrogen, careful local anesthesia of the pleura and proper observation of the manometer. Not until the latter records free oscillations with persistent negative mean pressure can one feel sure that gas may be introduced safely, unless one is using the open method.

INDICATIONS AND CONTRA-INDICATIONS

If one seeks a consensus of opinion on the cases which are appropriate for induced pneumothorax, he will soon see that a great difference of opinion prevails. Practically all observers agree that we have in pneumothorax an excellent means of controlling hemoptysis. In the few cases of hemoptysis that I have treated by this method, the result has been immediate success.

The presence of fever, even high, is not a contra-indication for induced pneumothorax. On the contrary, the temperature frequently drops under this treatment with surprising promptness.

The presence of fluid in the sac must be regarded as Nature's effort tending toward the same end as pneumothorax, namely, to secure lung rest, and is therefore to be removed only when symptoms demand intervention. On the other hand, a small effusion may be augmented by adding gas, thus inducing more complete lung rest.

Pleuritic adhesions, if extensive, constitute a mechanical barrier of a serious kind. Extensive adhesions prevent lung collapse and render pneumothorax impossible. If only partial, they may sometimes be broken down by gas pressure, carefully applied, or perhaps sufficient free pleura may exist to allow of a therapeutic result.

All writers agree that laryngeal tuberculosis is not a bar to the treatment. The larynx usually improves as the lung improves, but tuberculous infection of the bowels is a grave complication. Nevertheless, some report improvement even in these cases.

If the patient is already dyspneic, pneumothorax is *a priori* irrational, unless the dyspnea is attributable to the toxin and not to the limited lung area. Generally, such cases are unfavorable.

Miliary tuberculosis is regarded as a contra-indication, and so are serious cardiac disorders and marked splanchnoptosis.

The main discussion has centered on the question of how early in the course of pulmonary tuberculosis the patient should begin this treatment. While at present most writers agree that the best results are to be expected in unilateral cases, still they are not willing to restrict its application to this class of cases, nor are they willing to recommend its use in the early stages. It is therefore reserved for moderately advanced unilateral cases, and for some bilateral cases. Still I note that there is a growing tendency to extend the treatment to earlier cases, and to grant what alleviation it may offer even to those in the last stages. Some surprising results have been recorded in this class, usually considered as hopeless; but before expressing myself on these points let me quote a few authors on the indications and contra-indications.

Forlanini regards as favorable the uncomplicated unilateral cases free from pleural adhesions (unless these can be cleared by gas pressure) running a slow or subacute course, and provided the lesions are not far advanced. Claude Lillington admits cases of extensive and acute disease if unilateral, or nearly so; but he also finds that some cases with extensive bilateral disease are benefited. Klemperer says to try medical treatment first, but not to wait too long. He confirms the indication in unilateral cases, and thinks that the best results are in moderately severe cases, but in a comparatively early stage. Still he advocates the procedure in all cases with continuous fever and much expectoration, when the condition is not too desperate. Herbert Rhodes recognizes its value in recurrent hemoptysis, in unilateral cases and in some bilateral cases. Volhard endorses the suitability of unilateral cases even though involving the whole lung. He also endorses the treatment in bronchiectasis, but finds abscess and miliary disease contra-indications. Robinson and Floyd say: "Certainly the unilateral cases are the best adapted and promise the best results; but many of the good results reported by Brauer and Spengler in their series of 102 cases have occurred in bilateral cases. None of our own group were strictly of unilateral involvement, and yet the progress of six cases is most promising." Shortle reports much improvement in fourteen out of twenty-two cases, although all the patients were advanced in disease.

From the evidence thus far adduced, it seems to me that authorities disagree widely. If one decides to require prolonged medical treatment in early cases before resorting to pneumothorax — if the early cases are to be refused — then it seems to me that the treatment will be restricted almost entirely to progressed bilateral cases. For I have yet to see my first case of extensive unilateral disease without demonstrable infection of the opposite side. I believe that in the selection of cases, their classification into early or moderate or advanced is not of so much importance as is *individualization*. Some cases in each class are suitable for pneumothorax, and some in each class should be refused. To my mind, experience has already demonstrated this. On the other hand, if the theoretical explanation of the *modus curandi* of pneumothorax is correct (and I believe that it is correct), and if in this procedure we are following in Nature's own footsteps, securing physiologic rest in a disease in which the value of rest is amply demonstrated, and if we are squeezing infective material from the lung, encouraging fibrosis, discouraging hemorrhage, lessening toxemia and ridding the sputum of tubercle bacilli (all of which seems to be proved), then one queries why this treatment is not applicable to the early cases. The only reply is that a large proportion of early cases are curable by other means. But it seems to me that when we find ourselves face to face with a disease as serious as pulmonary tuberculosis, even though in an early stage, we should consider well before refusing pneumothorax, a treatment that has arisen from observation of Nature's cures, a treatment based on a rational theory, a treatment that offers a resultant lung pathology that proves its value, and a treatment that has yielded 22 per cent. clinical cures when limited to advanced cases.

After having come to this conclusion I was much interested to read what Murphy, the American discoverer of induced pneumothorax, wrote. He stated that it was especially applicable to "apical or monolobar tuberculosis in the early stage, as the pathologic conditions are such that the compression of the lung can be accomplished and adhesions are not likely to be found. I do not consider," he continues, "that it is indicated or practical in advanced or chronic tuberculosis, as the fibrous tissue deposited in the lung will not permit compression of the lung, nor will the pleuritic adhesions allow of gas introduction." In a more recent article Murphy has reiterated these early views.

As a matter of fact, practically only well-progressed cases have been treated by this method, although they offer the least promise. All my cases were advanced in disease. Before stating my results I will quote a few reports of other workers in this field:

Walker and Soltau reported 13 cases, in all of which there was improvement. Zubini reported favorable results in a series of 43 cases. Murphy reported 5 cases, all improved. Many of Lempke's patients were greatly improved and some cured. Robinson and Floyd reported 25 cases all improved. Lapham reported 31 cases, 68 per cent. arrested, 2 cured. Brauer reported 102 cases, 22 per cent. cured.

Murphy stated recently that from a study of 500 collected cases with 2,500 injections, he concludes that artificial pneumothorax should always be made in every case of pulmonary tuberculosis in which there is no absolute contra-indication. I have no hesitancy in concluding that when properly performed, with careful technic, by one who is experienced, the procedure is quite safe and practically painless. When not curative it is very often alleviative, affording an otherwise hopeless case a new chance for arresting the disease.

My experience is limited to forty-two cases, all but one bilateral and well advanced. All but one were ambulant, the patients coming to the office for treatments.

Of the forty-two cases, it is noteworthy that pleuritic adhesions prohibited pneumothorax in only five.

The total number of punctures done was over 614, and no gas embolism occurred; but pleuritic effusion supervened in six cases, one being purulent.

Twenty-two patients gained weight and eleven lost weight, this observation being unrecorded in four cases.

In the thirty-seven cases in which a pneumothorax, even though small, was possible, twenty-eight patients were improved in varying degrees, one was arrested (perhaps cured) and ten remain unimproved.

Oakland Bank of Savings Building.

Wages and Hygienic Living.—Regular employment at wages sufficient to meet the cost of hygienic living is the sine qua non of all the requirements. It does not take an expert in disease prevention to tell us that an underfed, poorly clothed, poorly housed group of people are going to prove easy prey to the germs of influenza, pneumonia, tuberculosis and similar diseases. Neither does it take a deep and prolonged study of wages, cost of living and housing conditions of the working people of the United States for us to know that a large percentage of them are living on a scale greatly below a hygienic minimum.—B. S. Warren in *Pub. Health Rep.*

THE GERMICIDAL ACTIVITY OF CALOMEL *

JAY FRANK SCHAMBERG, M.D.
AND
JOHN A. KOLMER, M.D.
PHILADELPHIA

While conducting investigations concerning the germicidal activity of chrysarobin and other substances used in the treatment of psoriasis, we were required to devise a technic suitable for testing substances which are insoluble in water. All of the methods generally employed in testing germicides require that the substance be soluble in water, weak alcohol, weak alkaline solutions, etc., which in themselves have little or no germicidal activity.

Since calomel is practically insoluble in water we have selected it as a control and have determined its germicidal activity on ordinary test micro-organisms.

After considerable experimentation, we have during the past year worked out a technic for determining the germicidal activity of insoluble substances which is very simple and yields surprisingly uniform results. It is not so perfect as the Rideal-Walker or Hygienic Laboratory methods for testing soluble substances, and it does not attempt to distinguish between antiseptic action and germicidal power; but for insoluble substances it has yielded us fairly good results.

Early in the work we were surprised to find that calomel had a germicidal activity equal to that of mercuric chlorid, and further studies have shown that several other insoluble salts of mercury have similar germicidal values.

In this note we wish to present the results of these studies with various mercurial salts, together with a brief description of the technic, a fuller account being given in another paper.

TECHNIC

A difficulty in working with substances insoluble in water is the preparation of a suspension such as will remain uniform for at least an hour or until all manipulations have been finished. We have found a sterilized 2 per cent. solution of acacia in water to answer this purpose most satisfactorily; the substance to be tested is accurately weighed and placed in a sterile flask containing a layer of small glass beads, the required amount of acacia solution being added and a suspension secured by agitating or shaking the flask for several minutes. All measurements of the suspension are made with sterile graduated 1-c.c. pipets. When working with calomel we have found that very little adheres to the sides of the pipet; but with chrysarobin and similar powders, it may be necessary to wash out the pipet once or twice with either sterile bouillon or normal saline solution.

During the time necessary for measuring varying quantities of the suspension, the flask should be occasionally shaken in order to keep the contents uniformly suspended.

We have used various test micro-organisms; since the primary object of our work was concerned with chrysarobin and its action on the skin, we have usually worked with cultures of staphylococci; however, a culture either of *Staphylococcus aureus* or *Bacillus*

---

* From the Pathological Laboratory of the Dermatological Research Department, Philadelphia Polyclinic and College for Graduates in Medicine.

typhosus may be used. The test micro-organism is cultivated in neutral bouillon for twenty-four hours at 37 C. (98.6 F.), filtered to remove clumps, and used in a constant dose of 0.1 c.c. as delivered by an accurately graduated 1 c.c. pipet.

Both plain neutral bouillon or plain neutral agar may be used for the seed medium. Best and most uniform results were secured with the former. Each tube contains exactly 10 c.c. of the medium.

The technic is very simple. In the *plate method,* increasing amounts of the suspension as, 0.05, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9 and 1 c.c. are pipetted into a series of twelve sterile Petri dishes; 0.1 c.c. of a twenty-four-hour bouillon culture of the test organism is added, followed by 10 c.c. of melted agar cooled to 40 c.c. The whole is thoroughly mixed. The twelfth plate receives culture and agar and serves as the culture control.

At the end of twenty-four hours the plates are inspected. The control usually shows so many colonies that it is impossible or inaccurate to count them. When germicidal activity is manifest there occurs a numerical decrease in colonies easily determined by counting.

By use of a 4-mm. loopful of bouillon culture in each plate the number of colonies is much reduced and accurate counting facilitated, especially in those plates which show germicidal activity of the substance being tested.

When working with large doses of a light powder it is impossible to determine by mere inspection of the plate whether or not germicidal action is manifest. In such instances, or when in doubt, we have cut out a block of agar with a stout platinum loop from the center of each dish and macerated this on a slant of neutral agar; the final result of the test is therefore delayed another twenty-four hours.

Better, sharper and more definite results are secured when the tests are conducted with a fluid medium. To a series of twelve tubes, each containing 10 c.c. of plain neutral bouillon, increasing amounts of the suspension of substance as given above are added; after each addition the pipet may be washed out once or twice by drawing up and expelling bouillon; to each tube there is added 0.1 c.c. of the test culture; the twelfth tube is the culture control and should never be omitted. The tubes are incubated for twenty-four hours, when the results are read. One is surprised with the regularity and sharpness of the results; even with slight differences in the dose of germicidal substances the tubes either do or do not show uniform clouding due to bacterial growth.

Of course in either method the culture controls must show good growths, as they usually do when working with *B. typhosus* or *Staphylococcus aureus.*

In this method the final dilutions vary when increasing doses of suspension are added to constant amounts of bouillon. We placed the desired amounts of suspension in a series of twelve dry sterilized tubes and pipetted in increasing amounts of sterile bouillon to make the total volume in each tube the same and equal to 10 c.c., but the results were practically the same when tried out parallel with the simpler procedure described above.

With the bouillon-tube method the results with the same substance from day to day are remarkably constant.

We have adopted calomel as a standard and have been able to express the relative values of other substances in comparison.

In the Hygienic Laboratory method of testing germicides the test organism is exposed to the action of the germicide for varying intervals of time as 2½, 5, 7½, 10, 12½ and 15 minutes, after which a loopful of micro-organisms and germicidal solution are removed and planted in bouillon. One loopful is, therefore, so highly diluted in the seed bouillon that any question of continued germicidal activity can practically be ruled out, unless the solution is highly concentrated. In our method it is not a simple matter to remove the germicidal substance and separate the test micro-organism. We have done so by different filters, but the technic is not uniform or practical. The micro-organism is continuously exposed to the germicide and in this manner we are unable to differentiate between antiseptic and germicidal action, for a substance may inhibit the growth of a micro-organism without necessarily killing it. As we have shown in our complete paper, this question of length of exposure is quite important. For example, 0.005 gm. of sodium arsenate inhibits the growth of staphylococci according to our method, whereas this salt shows no inhibiting or germicidal action by the Hygienic Laboratory method even in concentrated solution (1:5) after the maximum exposure of 15 minutes.

Throughout the remainder of this communication we speak of the "germicidal" activity of various substances; with calomel we have demonstrated that this terminology is correct; with many other substances, however, we have not so far attempted to differentiate between their antiseptic and germicidal power.

CALOMEL

We were surprised to find that calomel has a germicidal activity equal to that of mercuric chlorid. Naturally our first thought was that the preparation we were using (Merck's) might have contained traces of mercuric chlorid responsible for this result. But chemical tests for mercuric chlorid in heavy suspensions of calomel before and after filtration through Berkefeld filters did not show the presence of this substance. Likewise it was considered possible that hot agar or some chemical in the culture-medium might have rendered the calomel soluble or have changed it to a soluble salt; but careful and repeated experiments have shown that this does not occur. Furthermore, after a calomel suspension has been shaken mechanically for an hour at 42 C. (107.6 F.) and is filtered through a Berkefeld filter, the filtrate does not possess germicidal activity.

TABLE 1.—GERMICIDAL POWER OF CALOMEL

Calomel Suspension c.c	Equivalent in Weight gm	24-Hour Bouillon Culture of Staph. Aur. c.c.	Sterile Bouillon c.c.	Results after 24 Hours at 37 C.
0.05	0.000005	0.1	10	+
0.1	0.00001	0.1	10	+
0.2	0.00002	0.1	10	+
0.3	0.00003	0.1	10	+
0.4	0.00004	0.1	10	+
0.5	0.00005	0.1	10	—
0.6	0.00006	0.1	10	—
0.7	0.00007	0.1	10	—
0.8	0.00008	0.1	10	—
0.9	0.00009	0.1	10	—
1.0	0.0001	0.1	10	—

Table 1, one of many similar experiments, shows the remarkable germicidal power of calomel on *Staphylococcus aureus.*

Ten mg. of calomel were suspended in 100 c.c. of acacia solution. Each cubic centimeter contains, therefore, 0.0001 gm., or 1/600 grain.

It will be observed that 0.05 mg. (0.00005 gm.) or 1/1200 of a grain of calomel is capable of sterilizing 0.1 c.c. of staphylococci in 10 c.c. of bouillon.

A similar effect was noted with cultures of *B. typhosus* and *B. coli;* 0.1 c.c. of anthrax culture required at least 0.004 grain of calomel to bring about their destruction.

We have no explanation to offer of the mechanism of so high a germicidal activity of a substance insoluble in water. On first thought it would be supposed that each particle of germicide must come in actual contact with each bacterium; but this explanation can hardly hold when 0.00005 gm. of calomel spread out in 10 c.c. of agar in a Petri dish or in bouillon completely inhibits or kills the cocci contained in 0.1 c.c. of a twenty-four-hour bouillon culture.

OTHER MERCURIAL SALTS

An application of the same method to a study of the germicidal activity of other salts of mercury such as ammoniated mercury, red and yellow oxids, red and yellow iodids, etc., has shown them to possess a germicidal activity equal to calomel and mercuric chlorid.

Table 2 is included to show the comparative values of these mercurials and other soluble and insoluble substances, as determined by us. The figures refer to the smallest amount of substance required to inhibit the growth of 0.1 c.c. *Staphylococcus aureus.*

TABLE 2.—GERMICIDAL DOSES OF VARIOUS SUBSTANCES*

Substance	Amount in Grams	
	Bouillon	Agar
Yellow iodid Hg	.00004	.00004
Calomel	.00005	.00005
Red iodid Hg	.00005	.00004
Red oxid Hg	.00005	.00004
Mercuric chlorid	.00005	.00004

* One-tenth c.c. of twenty-four-hour-bouillon culture of *Staphylococcus aureus.*

† Not germicidal in maximum dose of 0.12 gm.

‡ Cubic centimeters.

It will be noted that most of the mercurial salts have a constant germicidal activity which is practically equal to that of mercuric chlorid. Taking calomel as a standard, the efficiency of other insoluble substances is readily expressed as the "calomel coefficient."

From a number of fragmentary reports given us by various clinicians who have at our suggestion used calomel suspensions in the treatment of various suppurations, we would suggest the use of calomel suspended in sterile acacia solution in the treatment of cystitis and pyelitis, and in suppuration of joints and sinuses. We would tentatively suggest a dosage of calomel of from 1/10 to 1 grain to the ounce in 2 per cent. acacia solution.

The one main difficulty in the therapeutic use of calomel suspension in acacia-water is the fact that sedimentation begins within from half an hour to an hour. If, however, the suspension is prepared in a bottle it may be readily shaken just before use and permits being injected into the bladder, accessory sinuses, etc.

CONCLUSIONS

1. The method herein proposed for testing the germicidal activity of substances insoluble in water is very simple and yields constant and reliable results; it offers a means of determining comparative values with calomel as a standard, the result being expressed as the "calomel coefficient."
2. Despite the insolubility and relative non-toxicity of calomel, its germicidal power, weight for weight, equals that of mercuric chlorid. Certain other mercurial salts are equally germicidal.
3. Suspensions of calomel offer considerable hope of various cavities.

1922 Spruce Street—927 South Bernard Street.

SPONTANEOUS RUPTURE OF THE HEALTHY ESOPHAGUS

IRVING J. WALKER, M.D.
BOSTON

Because of the interest stimulated by the observation of a case and the apparent rarity of this condition, I have reviewed the literature on this subject.

Spontaneous rupture of the healthy esophagus should include those cases of rupture *per se,* and exclude those in which the rupture has been due to trauma either from within or without, and also cases of perforation, the result of chronic peptic ulcer diverticulum, tuberculosis, syphilis, cancer and aneurysm. In selecting cases one must also reject those in which there has possibly been post-mortem digestion of tissue and those cases of esophagomalacia. Failure to eliminate such may lead to erroneous conception of the disease. For this reason I have not included the cases reported by Colegrove,[1] Heyfelder,[2] Guersent,[3] Lomax,[4] Oppolzer,[5] Howse,[6] Boyd,[7] West and Andrews,[8] and Bailey.[9]

ETIOLOGY

The disease is most frequently seen in men who are addicted to alcohol. How much influence the latter has on the condition has never been determined. In practically every case rupture has followed vomiting or retching after an abnormally large meal. The point of rupture in every case has been just above the diaphragm. In this small section of about 5 inches there is a transition from the esophagus. Also, we learn from the experimental work of McKenzie[10] that this is the weakest section of the esophagus and, furthermore, it is weaker than the normal stomach; but why the esophagus at this point should be weaker in a few persons than in others is not demonstrated. Some maintain that there is always disease in such cases.

RUPTURE OF ESOPHAGUS

No.	Sex	Age*	Alcohol†	Previous History	Onset	Symptoms	Emphysema	Duration of Life, Hours	Shape and Position	Results of Necropsy	Authority and Date
1	♂	50	?	Gouty; heavy eater, accustomed to emetics	Sudden, while vomiting	Felt something give way; intense pain; collapse; dyspnea	+	13	Complete transverse rent 3 fingers' breadth above diaph'gm	Collapse of the lung; air and gastric contents in both pleural cavities	Boerhaave[12] 1724
2	♂	?	+	Debauch the previous night	Sudden, after taking hot water to induce vomiting	Felt something give way; slightly hematemesis, severe pain, dyspnea; collapse	+	12	Longitudinal slit just above diaphragm admitting 2 fingers	Double pneumothorax; gastric contents in both pleural cavities	Dryden[13] 1787
3	♂	24	+	Severe epigastric pain and vomiting for several months	Sudden, during vomiting after dinner	Slight vomiting; severe epigastric pain	+	14	Large rent just above diaph'gm	Food found in pleural cavity	King[14] 1843
4	♂	38	+	Took lye when a child, since then difficulty in swallowing	Sudden, in attempting to swallow sausage which became impacted	Some hematemesis pain and dyspnea after effort to vomit	+	50	Gaping rent 1¼ by ⅜ in. about 3 inches above cardia	Gangrenous cavity in posterior mediastinum; food in both pleural cavities	Meyer[15] 1858
5	♂	35	+	Gastric disturbance for 6 wks. before	Sudden, after a debauch	Vomited at first; pain, dyspnea; collapse	+	11½	Longitudinal tear 5 cm. long encroaching on stomach	Double pneumothorax; gangrenous cavity in posterior mediastinum; fluid in pleural cavities	Gramatzki[16] 1867
6	♂	49	±	Not given	Sudden, after abnormally large meal	Felt something give way during vomiting; pain, dyspnea; thirst; collapse	+	16	Longitudinal slit 1 inch long just above the diaph.	Three quarts of fluid containing food in left pleural cavity; lung collapsed	Griffin[17] 1869
7	♂	35	+	Drinking hard for several days before onset	Sudden, after vomiting	Felt something give way; pain; dyspnea; thirst; collapse	‡	7½	Slit 1½ in. long in left side of lower esophagus	Gangrenous cavity in posterior mediastinum opening into left pleural cavity contained 1 qt. of fluid.	Charles[18] 1870
8	♂	31	+	Repeated attacks of gastritis; hematemesis delirium tremens	Sudden, in trying to dislodge a piece of meat impacted in esophagus	Pain and dyspnea; fever	+	180	Rent 2 inches long	Infection of posterior mediastinum	Fitz[11] 1877
9	♂	17	—	Attacks of blood-poisoning short time previously	Sudden, during vomiting	Hematemesis; intense feeling of suffocation; pain; collapse	?	4	Rent 1½ cm. long 1 in. above cardia	Opening into left pleural cavity which contained food particles	Taendler[19] 1878
10	♂	53	—	Dyspepsia for yrs. with occasional vomiting	Sudden, after feeling unwell for 2 hours after a meal	Severe pain in left side and sudden collapse	‡	7	Rent in posterior wall 1½ inches above diaph'gm	....	Adams[20] 1878
11	♂	48	?	Chronic gastric ulcer	Sudden	Vomiting followed by pain and collapse	—	15	Opening 2 inches long and 1 cm. wide about 2 cm. above cardia	Double pneumothorax; food in posterior mediastinum and both pleural cavities	Lindermann[21] 1887
12	♂	37	+	Good eater; alcohol moderate	Sudden nausea; felt something give way	Pain, collapse, cyanosis	+	Few	Clean tear 1 cm. long just above cardia	Left pleural cavity filled with food and gas	Wolff[22] 1894
13	♂	47	—	Dyspeptic; vomiting	Sudden, while vomiting	Pain, collapse, disappearance of cardiac dulness	+	13½	Rent 1½ inches long just above cardia	Left pneumothorax; stomach contents in both pleural cavities	Harrison[23] 1893
14	♂	55	‡	Healthy individual	Sudden, after vomiting	Pain, dyspnea, cyanosis	—	24	Rent ¾ inch long behind and to left	Food in left pleural cavity	West and Andrews[24] 1897
15	♂	59	+	Drinking hard for a week before	Sudden	Pain, dyspnea, effusion into left	+	37	Opening 1½ ins. long 2 inches above cardia	Accumulation in posterior mediastinum breaking into left lung but not the pleural cavity	Lindsay & Smith[25] 1899
16	♂	43	?	"Quiet"	Sudden vomiting after eating	Collapse	?	6	Rent 2 cm. long 6 cm. above cardia	Food in left pleural cavity	Heintze[26] 1900
17	♀	62	—	?	Sudden, after induced vomiting	Internal epigastric pain; dyspnea; collapse	+	22½	Rent ⅝ inch long 1½ ins. above diaphragm	Collapse of lung; food in posterior mediastinum and left pleural cavity	Bowlers & Turner[27] 1900
18	♂	40	+	Drunkard; much vomiting	Sudden, probably during vomiting	Pain, dyspnea, cyanosis, collapse	+	10	Rent 1½ ins. long just above diaphragm extending into stomach	Collapse of lung; food and gas in posterior mediastinum and left pleural cavity	McWeeney[28] 1900
19	♂	55	+	Fell from horse, fracturing skull. Operation	Sudden, vomiting after coming out of anesthetic	Not known	—	10	Rent 1½ inches long just above diaphragm	Food in left pleural cavity	Whitman[29] 1903
20	♀	10	—	Always well	Sudden, during sleep	Nausea, cyanosis, shock	—	18	Rent 1 cm. long 5 cm. above diaphragm	Food in left pleural cavity	Miller[30] 1911
21	♂	43	?	?	Probably during anesthetic	Cyanosis, shock	—	11	Ragged rent 3 ins. above diaphr'gm	Right lung collapsed; stomach contents in posterior mediastinum and right pleural cavity	Roy[31] 1911
22	♂	39	—	Always well	Sudden, one hour after large meal	Shock, cyanosis	—	176	Rupture 2 inches long at lower end of esophagus	Fluid in left pleural cavity	Walker 1914

* In this column ♂ denotes male, and ♀ female. † In this column + means yes, — no, and ± probably. ‡ Not stated.

From observation of the case reported and data from two others, I believe that it may be a developmental condition associated with ptosis of the viscera. An explanation of this theory, however, should be reserved until further study has been made from necropsies on subjects having visceral ptosis.

Granted that this section of the esophagus is weaker than any other and also weaker than the stomach, rupture has been explained to take place in one of the following ways: During the act of vomiting or retching there is spasm of the esophagus above the weak point. If the pressure from within is less than is needed to overcome the spasm and sufficient to cause rupture, the latter takes place. Secondly, if food becomes impacted in the esophagus above the weak section during the act of vomiting, and similar conditions of pressure are brought to bear on this area, rupture will occur.

PATHOLOGY

The rent in every case has been at the lower end of the esophagus and longitudinal in all except two cases. Usually there is a single opening on the posterior wall. This leads into the cavity of the posterior mediastinum, which may contain food particles. In the majority of cases this cavity communicates with one or both pleural cavities, which also contain liquid and solid food tinged with blood.

DIAGNOSIS AND PROGNOSIS

Difficulty in making an early diagnosis in this condition is due to the fact that the symptoms are referred to the upper abdomen and not to the esophagus. Most patients give a history of alcoholism with chronic gastric disturbance, of having vomited after a large meal, and during the effort experience the feeling of "giving way" in the upper abdomen. The patient is in a state of marked shock with subnormal temperature, high pulse, profuse sweating and some cyanosis. The respirations are usually slightly elevated. The face is drawn and anxious and the patient lies or sits with the knees drawn upward. Pain is referred to the epigastrium and lower chest, either on the right or left, but usually the latter. There is marked tenderness and board-like rigidity throughout the upper abdomen. Chest examination may show a few râles at the base and sometimes hyperresonance or flatness on percussion depending on whether there is much air or fluid in the pleural cavity. The picture up to this time is that of acute perforation of a gastric or a duodenal ulcer or acute pancreatitis. As time goes on, and especially if the patient has swallowed any liquid, the symptoms point more to some chest condition. The respirations become rapid and shallow, and the temperature elevated. The chest-signs spoken of above become more pronounced and the heart pushed to the right, the area of heart dulness practically obliterated. Aspiration of the chest will reveal fluid and gas. If the former is examined microscopically, food particles may be distinguished. In some cases there will be emphysema of the chest and neck. In the series of cases reviewed, mine was the only one diagnosed during life, and that wrongly at first.

The prognosis in this condition is grave. Not a single case of recovery has been reported. Most patients die within twenty hours. The one reported by Fitz[11] lived 180 hours.

TREATMENT

Very little except palliative measures can be found in the literature concerning treatment of this condition. From the observation of my case, it does seem possible that should the diagnosis be made early, there might be some chance of saving the patient by approaching the lesion through the posterior mediastinum, repairing the rent and draining the mediastinum and pleural cavity. Such an operation, however, would add much shock to a patient already in that condition so that recovery would be questionable. Even should the patient survive the operation a few days, one still has to combat sepsis in the posterior mediastinum, pleural cavity and lung-tissue. As yet, operative measures look none too bright. The case reported below occurred in my practice.

REPORT OF CASE

Patient.—A Swedish granite-cutter aged 39, was seen in consultation with Dr. Dion of Quincy at 1:30 a. m. March 16, 1914. Family history was negative. Patient had always been well. He had never used alcohol in any form.

Present Illness.—About seven hours before being seen patient had eaten an unusually large meal and taken two drinks of whisky. About one hour later he vomited. During this effort severe pain was felt in the epigastrium and left lower chest.

Examination.—Patient is well developed and nourished, somewhat cyanotic, and face has anxious expression. Pulse 120, temperature 97.6, respirations normal. Whole abdomen rigid but especially the upper half where there is marked tenderness and spasm. Liver dulness present.

Operation.—Incision 6 inches long at the outer border of the right rectus muscle over the gall-bladder region. Liver apparently enlarged, lower border of right lobe being on a level with the crest of the ileum, lower border of stomach about 1 inch below level of umbilicus. Appendix, stomach, duodenum, spleen and kidneys normal. Gall-bladder distended, ducts patent. Cholecystostomy performed; cigaret drain to head of pancreas which seemed swollen. Wound closed in layers.

Postoperative History.—During the next few hours the temperature and respirations became elevated. When patient was seen at 4 p. m. the pulse was 140, temperature 103, respirations 40. There was flatness in the left chest from the middle of the scapula downward and diminished and distant breathing in this region. Aspiration of the chest gave a straw-colored fluid. As it was thought that this was a beginning empyema, the pleural cavity was drained by resecting a piece of the eighth rib. The respirations at once were lowered. On the following morning, March 18, the nurse reported that all the nourishment taken was passing through the opening in the chest wall. March 19, a gastrostomy was done under novocain anesthesia and the patient afterward fed in this way. Temporary improvement followed feeding but the patient succumbed March 23, at 12:30 a. m., about 172 hours after the rupture of the esophagus.

Necropsy.—March 23, ten hours after death by Drs. Middleton and Ahlstrom. Well-nourished male, 6 feet tall, weight 165 pounds. Incision of operation 6 inches long slightly to right of median line starting 2 inches above umbilicus and extending upward from which hepatic fluid was escaping. There was a parallel incision 2 inches to the left of the median line 1 inch long. Incision in left back in midscapular line 1 inch below scapula and 2 inches in length. Liver enlarged, necrosis of lower border of right lobe. Gall-bladder macerated. Stomach incised and sutured to abdominal wall at site of smaller incision, evidently for feeding. Abdominal and pelvic viscera below liver apparently normal. Entire back and outer side of right lung adherent to chest wall. A few pleural adhesions at back of left lung. Left pleural cavity contained, throughout its extent, a thick, sticky, grayish-yellow fluid. There is a rupture of the extreme lower end of the esophagus, 2 inches in length, extending upward from the cardiac end of the stomach. Rupture on posterior wall of the esophagus. Edges of rent clean-cut, no evidence of ulcer, new growth or diverticulum.

---

[11] Fitz: Am. Jour. Med. Sc., 1887, lxxiii, 17.

A brief review of the unquestionable cases reported in the literature follows: Number of cases, twenty-two; males, twenty; females, two. Average age, 41.3 years. Of the males eleven were addicted to alcohol, four were abstainers, four were questionable and one not stated; neither of the females used alcohol. Emphysema was present twelve times, absent six times, questionable in two, not stated in two. No patient recovered, the average duration of life being 30.4 hours.

CONCLUSIONS

1. Spontaneous rupture of the apparently healthy esophagus is a rare condition.
2. The exact cause is not known.
3. Accurate diagnosis is difficult to make.
4. The mortality will always be high.

527 Beacon Street.

FOUR YEARS' EXPERIENCE WITH SALVARSAN AND NEOSALVARSAN IN THE TREATMENT OF NERVOUS DISEASE DUE TO SYPHILIS *

C. BURNS CRAIG, M.D.
Chief of Clinic, First Division
AND
JOSEPH COLLINS, M.D.
Attending Physician, Neurological Institute
NEW YORK

Soon after the release to the profession of Ehrlich's first synthetic arsenic product, the ultra-enthusiastic gave forth the cry to the carrier of the *Spirochaeta pallida* that the *salvator hominum* had been found. The extremely conservative held the more tenaciously to mercury, the approved therapy of centuries, and pessimistically pictured the dangers of salvarsan. While as yet our conclusions may not be beyond the pale of dispute, it may prove valuable to make a reckoning of the experience of four years in the continuous use of the powerful drug. That a new era in the treatment of syphilis has been entered there can be no doubt. The discovery by the lamented Schaudinn, the dark-field microscope and the ingenious adaptation by Wassermann of the Bordet-Gengou biochemical reaction have set our feet on firm rock in our determination of skin and visceral syphilis. Colles' law has been given the lie; Profeta's dogma has been discarded. By the achievement of Noguchi and Moore the parasyphilitic wraith has vanished forever "into thin air," revealing the reality, the syphilogenous nature of general paresis and tabes, and making certain that the findings in the spinal fluid represent to a degree, in these cases, the ravages of the pale spirochete on the investments and substance of the central nervous system. It is from the treatment of three hundred cases of syphilitic affections of the nervous system that our conclusions shall be drawn.

The nervous system in most persons is particularly tolerant to the toxins of syphilis, or better said, the nervous system performs its functions patiently and faithfully without display of symptoms for from ten to thirty years while its very vitals are being destroyed by a chronic intoxication, before it finally manifests that all is not well. From this fact grew our misconception called latent syphilis. With our present laboratory aids we know now that evidence of invasion of the central nervous system may occur within a few weeks of the time of the initial lesion. Indeed, occasionally we meet a case in which even before the so-called cutaneous secondary rash has appeared, or while it is still present, the central nervous system has been overwhelmed and the fluid which bathes it shows a marked cellular exudate. This knowledge of the early invasion of the central nervous system forewarns us emphatically that the most auspicious moment for the treatment of syphilitic nervous affections is in that all-important time which may be termed the tolerant period.[1] This period having passed by and the toxin having been at work subtly for years in a subterranean manner, the defenses yield at last, and grievous evidence that the enemy is within the walls appears. It is at this point that the neurologist is usually summoned to combat the inroads of the invader. We can now, in a comparatively short period, proceed to check the invasion in a manner almost as cunning as the enemy's own methods and can preserve the integrity of that portion of the system which has not been actually destroyed. Having rid ourselves of the blighting delusion of the specificity of potassium iodid and of the futility of mercury by mouth, and even intramuscularly or by inunctions when given in the indifferent manner which has too long prevailed, we take hold eagerly of the new remedy which is more rapid, more certain and more complete in its action.

Salvarsan is not a panacea. Nothing could militate more against the correct evaluation of the efficiency of this remedy than its promiscuous use and the impression that a few doses of salvarsan will restore health in all cases of syphilitic nervous disease regardless of their duration and severity. We do not wish to give the impression that we would deny to any definitely syphilitic person the advantage of salvarsan treatment, but we do believe that it is unjust to both patient and remedy to promise or expect the regeneration of destroyed nervous tissue with restoration of function. For instance, to predict great improvement to a tabetic patient whose ataxia has existed for ten or fifteen years with pronounced hypotonus, vesical incontinence and negative serum and spinal fluid, is not only unfair, but is detrimental to the establishment of the true value of salvarsan. On the other hand, in the acute cases with symptoms more or less recent, with an active reactionary and inflammatory process in the tissues as revealed by the blood and spinal fluid, the therapeutic capability of salvarsan is often but little short of miraculous. When one encounters one day a man stricken down at his work, irrational and aphasic, and forty-eight hours later beholds him speaking and in his right mind, one cannot but believe that a potent agent has been applied. One is driven to a similar conclusion when one sees men come into the hospital on crutches and go out a few weeks later walking alone or aided slightly by a single cane, which is later discarded.

---

* From the Neurological Institute, New York.

[1] Graves: Med. Rec., New York, Aug. 24, 1912.

It is in the recent and acute cases that the use of salvarsan cannot be too strongly urged.

METHOD OF ADMINISTRATION

The use of salvarsan at the Neurological Institute was begun in June, 1910. Since that time upward of 1,500 administrations of salvarsan and neosalvarsan have been made on the First Division Service. The routine method of preparation and administration has been but slightly altered during these four years. The quantity of freshly distilled sterilized water has been reduced, 25 c.c. being used for each 0.1 gm. of salvarsan, and 10 c.c. for each 0.1 gm. of neosalvarsan. We are not convinced of any increased therapeutic value of concentrated dosage, such as giving a full dose in 10 or 20 c.c. of water; but such decrease in the quantity of fluid as we have made we believe can be done with safety and a considerable saving of time. Intravenous administration is the method of choice, the intramuscular method being usually painful, less prompt in its effects and often complicated by subsequent undesirable features, such as permanent induration or abscess. Cutting down on a vein is barbarous and unnecessary except in extremely corpulent persons with obscured veins, as with a little care a needle can be introduced into a vein in the cubital space without difficulty. In treating very young children the intramuscular method is sometimes necessary. In introducing salvarsan into the vein the gravity method has proved simplest and most practicable.

EFFECTS OF SALVARSAN

During the past twelve months we have had a growing conviction that the potency of neosalvarsan is not so great as that of salvarsan, so that we have returned to the use of the original preparation. The immediate after-effects of the newer compound are usually milder, but its curative value is also less. Others working with cases not neurologic have arrived at the same conclusion.[2] The immediate after-effects, when unpleasant at all, are limited to nausea or vomiting or the recurrence of tabetic pains, all of which with the aseptic precautions now used are comparatively rare. The latter symptom is probably due to the increased tension in the roots or root ganglia resulting from the influx of scavengering leukocytes which come in to carry away the recently killed spirochetes. Within twenty-four or forty-eight hours the patient usually experiences a feeling of well-being such as he has not had for some time, and if he has been having pains they have disappeared. In fact, after the first dose of salvarsan, tabetic pains which may have tortured the patient for a decade or more may disappear never to return. If we were called on to select the single greatest benefit which follows the use of salvarsan, it would be the relief obtained by the disappearance of the hideous pains of tabes. Man can endure almost any disability if he is free from pain. Fortunately, that is not the sole benefit, but that is usually the first lasting improvement. Subsequent improvements and final results following the administration of salvarsan in nervous diseases of syphilitic origin depend entirely on the character and duration of the disease.

TROPHIC DISEASE

Forms of disease styled trophic, such as Charcot joint, have given very little encouragement that a remedy has been found in salvarsan. The insufficiency of the therapy becomes apparent when one sees the disintegrating process in the joint go steadily on even though the serologic vestiges of syphilis have been rendered negative.

CEREBRAL ENDARTERITIS

Another variety of case resulting from syphilis, which is treated with meager success, is cerebral endarteritis which has gone on to thrombosis or rupture. The hemiplegic patient is usually seen in a neurologic clinic some weeks or months after the "stroke," after the edema around the lesion has largely subsided. If syphilitic, he will show a positive Wassermann in serum or spinal fluid or both, but a cellular exudate in the spinal fluid is almost always wanting. True, an endarteritis may occur in a tabetic or a cerebrospinal luetic patient, in which case the spinal fluid will show an increase in cells. The cells may be caused to disappear and the Wassermann to become negative, but salvarsan has not been observed to affect to any considerable extent the symptoms resulting from the arteritis, allowing for the slight improvement which usually occurs spontaneously. Endarteritis, occurring early in the disease and giving rise to focal symptoms, usually yields quite readily to salvarsan therapy, if an area of softening has not already occurred.

SENSORY-TRACT DISEASE

In a discussion of the results obtained in the treatment of tabes with salvarsan, the cases fall readily into two classes. First, those of long standing in which, besides the ataxia, marked hypotonus has developed, and an examination of the serum shows that the active inflammatory resistance on the part of the body has subsided either because the syphilitic process has been overcome, which is more probable, or because the tissues have become so used to the chronic intoxication that they no longer resist — in short, those cases in which the Wassermann reaction in serum or spinal fluid, or in both, is negative, and the cellular elements in the spinal fluid are absent or few, or only slightly above normal. The citation of a few such cases will serve best to make this clear:

---

[2] Nelson, Kent, and Haines, Edgar F.: Observations of the Results of Nine Months' Experience with Neosalvarsan at the United States Military Prison Hospital, Fort Leavenworth, Kan., The Journal A. M. A., March 28, 1914, p. 989.

CASE 1.—W. H., man, aged 44, married. Complaint: Unable to walk or stand alone. Urinary incontinence. Pain in the legs and arms, shooting in character. Numbness and tingling in the hands and feet. Belt-like sensation around the lower ribs, at other times around the abdomen.

Duration two and one-half years. Progressively worse. Chancre twenty-five years before.

Examination.—Marked ataxia and hypotonus; unable to stand alone. Absent tendon-jerks. Postural sensation in the lower extremities wanting. Argyll Robertson pupils and emaciation. Wassermann serum positive; Wassermann fluid negative; Globulin positive; Cells 56 per cubic millimeter.[3]

Treatment.—Salvarsan, 0.6 gm., three doses, and tonic measures.

Six months later the patient's condition was quite the same without any interval of appreciable improvement. Wassermann serum negative.

CASE 2.—L. M., man, aged 36, married. Complaint: Girdling pains in the right groin and shooting down the legs. Drawing and gripping in the back and arms, unsteadiness in walking. Polyuria and dysuria. Loss in weight and strength. Duration eight years. Chancre eighteen years before.

Examination.—Ataxic gait. Rombergism. Considerable hypotonus and impaired postural sense. Absent tendon reflexes and Argyll Robertson pupils. Wassermann serum positive; fluid negative; globulin negative; cells 3 per cubic millimeter.

Treatment.—Salvarsan, 0.6 gm., three doses; neosalvarsan, 0.9 gm., one dose.

Three years after the first dose the patient was still having attacks of the same pains, was markedly ataxic and showed the same physical signs. Wassermann serum negative; fluid negative; globulin negative; no cells.

CASE 3.—E. R., man, aged 53, widower. Complaint: Attacks of gastric pain. Pain of jerking character in the legs. Dysuria. Numbness in the soles. Duration seventeen years, progressively worse. Chancre twenty years before.

Examination.—Argyll Robertson pupils, slight Rombergism. Absent knee and ankle reflexes. Ataxia not marked. Wassermann serum negative, fluid negative; globulin negative; mononuclear cells 53.

Treatment.—Neosalvarsan, 0.9 gm., three doses; 0.45 gm., one dose, within three weeks.

Observation seven months later shows no alteration in the patient's condition. He still complains of the pains in his legs and numbness. The dysuria is possibly improved. Wassermann serum negative; fluid negative; globulin negative; no cells.

In the second class of tabetics the condition is of more recent development and usually the infection is more recent. To the majority of patients of this class a very good prognosis can be laid down, based, of course, on the serologic findings. Considerable difficulty often arises here in making a correct estimate of the case inasmuch as these are the patients who, during the past decade, have been the rounds of mercury pills and potassium iodid drops. The inefficiency of the treatment "stands condemned by its eloquent results," as Fordyce[4] has so aptly put it. The difficulty lies in the fact that the iodid treatment may have affected the condition of the serum in its relation to the Wassermann reaction, which is our compass in directing antisyphilitic therapy, without having done any real damage to the spirochete. Fortunately for this particular feature, the patience of the average patient soon wearies of an oft-repeated remedy which produces no marked visible results, and so the reaction of the serum remains more or less unmodified by the "drops and pills" and is a true guide. In those cases favorable for treatment, hypotonus of the hip-joints has not developed, although vesical incontinence may be present as well as ataxia and impairment of the postural sense. These symptoms may disappear in whole or in part, but in many cases even after vigorous treatment, vestiges of the symptoms remain. In such cases the Wassermann reaction is usually plus in the serum, and plus or minus in the spinal fluid; the globulin excess is plus; mononuclear cells range from twenty to several hundred per cubic millimeter, and Fehling reduction is plus. The treatment in such a case does not consist in two or three injections of salvarsan, but aims to render negative the Wassermann reactions and to reduce the number of cells to zero. The most vigorous treatment may be necessary to accomplish this result. It may take five injections at frequent intervals, or it may take twenty more. One method which we employed was to give a series of four full doses of neosalvarsan with a forty-eight hour interval between doses, and then after two weeks to repeat this if necessary. This method we have given up and are now employing salvarsan in full doses every five or seven days for a greater or less period, being guided chiefly by the state of the spinal fluid, especially with regard to the cell-content. The following cases will illustrate this group:

CASE 4.—F. B., man, aged 47, married. Complaint: Pain in the back and legs, occasional vesical and rectal incontinence; depressed, speech halting at times, hands tremulous, morphin habit. Duration six years, progressive. Chancre seventeen years ago.

Examination.—Slight Rombergism, no ataxia, knee and ankle reflexes absent. Pupils unequal but respond to light. Wassermann serum negative; cerebrospinal fluid positive; globulin positive; mononuclear cells 90.

Treatment.—Neosalvarsan, 0.9 gm., four doses within one month. Observation three months later: Pains have disappeared. Has stopped morphin. General condition improved. No incontinence. Physical signs remain the same. Pupils sluggish. Now able to earn his living. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; cells 17.

CASE 5.—J. M., woman, aged 35, married. Complaint: Shakiness and weakness in both legs; pains in knees and legs; jerking in arms and legs at night. Drops articles from her hands. Drooping of left lid; dimness of vision. Duration five years. Stationary, lues denied.

Examination.—Slightly ataxic gait; Rombergism; Argyll Robertson pupils; left facial weakness. Hemorrhage into vitreous of right eye. Incoordination of arms. Knee and ankle reflexes absent. Wassermann serum positive; cerebrospinal fluid positive; globulin positive; mononuclear cells 42.

Treatment.—Neosalvarsan, 0.9 gm., three doses within three weeks. Observation nine months later: The ataxic gait has disappeared. Facial weakness gone. No Rombergism. Reflexes and pupils same; vitreous clear. Feels quite well. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; mononuclear cells 4.

CASE 6.—A. D., man, aged 45. Complaint: Weakness in right leg. Heaviness of right thigh and abdomen. Walking difficult.

Examination.—Ataxia, Rombergism; Argyll Robertson pupils, absent ankle and knee reflexes. Hypotonus of lower extremities. Hyperesthesia at sacral crests. Duration two months; progressive; lues denied. Wassermann serum negative; cerebrospinal fluid negative; globulin positive; mononuclear cells 81.

Treatment.—Salvarsan, 0.6 gm., two doses at interval of seven days. Observation one month later; walking easier and better, ataxia less. Slight heavy feeling still present, heavy in right thigh. Reflexes and pupils the same. Continues to work as salesman. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; mononuclear cells 8.

---

[3] In all the cases reported in this paper Fehling's solution was reduced by the spinal fluid.

[4] Fordyce, John A.: The Administration of Salvarsan in Syphilis, THE JOURNAL A. M. A., Oct. 5, 1912, p. 1231.

Case 7.—L. L., man, aged 36, married. Complaint: Loss of strength, pain and cold sensation in both legs. Vesical incontinence, tightness about the chest. Duration four years; progressive. Chancre fourteen years ago.

Examination.—Romberg; ataxia; walks with cane. Uncertain in sitting posture; moderate hypotonus in hips. Incoordination in arms and legs. Reflexes absent in biceps and triceps, knees and ankles. Argyll Robertson pupils; tactile anesthesia over lower extremities.

Wassermann serum positive; cerebrospinal fluid negative; globulin weakly positive; mononuclear cells 142.

Treatment.—Neosalvarsan, 0.9 gm., six doses within six weeks. Observation one year latter: Feels well; much less dependent on cane in walking. Paresthesia and pain gone. No vesical incontinence. Can attend to business.

Examination.—Romberg and ataxia less marked; other findings the same. Wassermann serum positive; cerebrospinal fluid negative; globulin negative; mononuclear cells 48.

Case 8.—M. V., man, aged 44, married. Complaint: Pain down the back of the legs and inability to walk without crutches. Duration 9 months; progressive. Lues denied.

Examination.—Walks uncertainly with crutches. Rombergism. Absent knee and ankle reflexes. Pupils irregular, unequal, very sluggish to light. Wasserman serum positive; cerebrospinal fluid negative; globulin negative; mononuclear cells 33.

Treatment.—Neosalvarsan, 0.9 gm., three doses. Observation one month later, improvement remarkable. Walks alone without crutch or cane. Ataxia scarcely noticeable. Reflexes and pupils remain unchanged. Lumbar puncture refused. Wassermann serum positive.

Case 9.—F. D., man, aged 47, married. Complaint: Paresthesia of left hand. Loss of power and control of legs; wasting of left leg. Pains in legs and in the bones. Urinary incontinence, walks with crutches. Duration eight years; progressive. Chancre twenty-six years ago.

Examination.—Ataxic gait, Rombergism. Partial paralysis left thigh and leg. Tremor of hands; incoordination of arms and legs. Knee and ankle reflexes absent. Pupils unequal, sluggish to light. Hypesthesia of legs. Wassermann serum negative; cerebrospinal fluid positive; globulin positive; mononuclear cells 135.

Treatment.—Salvarsan, 0.6 gm., five doses in four weeks. Observation three months later: Ataxia much diminished. Gait improved. No pain, paresthesia still present. Pupils sluggish to light. Knee- and ankle-jerks absent. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; mononuclears 32.

Case 10.—M. B., woman, aged 36, married. Complaint: Legs feel weak and trembly; pain down outer side of both calves, feet cold and numb; drops articles occasionally from left hand; difficulty in walking. Duration five years, getting worse recently. No knowledge of infection.

Examination.—Slight Rombergism, unsteady gait, slight hypotonus of hips and knees, incoordination and postural disturbance of lower extremities. Absent knee- and ankle-jerks, also gone in the arms. Argyll Robertson pupils. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; mononuclear cells 107.

Treatment.—Salvarsan, 0.6 gm., four doses in a month. Three months later felt much stronger, no pain; normal feeling in extremities, but had a girdle sensation; gait much improved but still some unsteadiness. Wassermann serum positive; cerebrospinal fluid negative; globulin negative; cells 13.

Treatment.—Salvarsan, 0.6 gm., one dose, and thirty inunctions of mercury. Five months later only one remaining symptom is slight unsteadiness in walking; pupils and reflexes unchanged. Romberg less. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; cells 5.

Case 11.—C. J., man, aged 50, married. Complaint: Pain in the middorsal region which starts in the back and runs around the trunk to the epigastrium. Jumping pains and soreness in the thighs. Tense, tight feeling about the abdomen; morphin regularly for pain. Duration seven years, progressive. Chancre twenty-seven years before.

Examination.—Rombergism, very slight ataxia, tremor in the hands, no hypotonus, left knee-jerk absent, right diminished, ankle-jerks gone. Argyll Robertson pupils. Wassermann serum positive; cerebrospinal fluid negative; globulin positive; mononuclear cells 42.

Treatment.—Salvarsan, 0.6 gm., three doses in three weeks, cauterization of the back. One month later patient was entirely free from pain and tight sensation; has taken no morphin and has no desire for it. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; cells 0.

Case 12.—F. G., man, aged 55, married. Complaint: Shooting pains in the legs, difficulty in walking; frequent desire to urinate, diplopia, band sensation about the waist, weakness of the back. Duration eighteen years; progressive; worse. Chancre twenty-six years ago.

Examination.—Very ataxic gait, marked Rombergism, incoordination of legs, absent knee and ankle reflexes. Argyll Robertson pupils. Wassermann serum positive; cerebrospinal fluid positive; globulin positive; mononuclear cells 42.

Treatment.—Salvarsan, 0.6 gm., three doses in ten days. One month later shows less ataxia in walking, is free from pain and girdle tightness and general feeling of more strength and vigor. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; cells 36.

Case 13.—E. L., woman, aged 50, married. Complaint: Sharp shooting pains through both lower extremities to the feet, also through the arms to the hands. Aching pains through the head recently, creeping feeling all over the body; numbness in the buttocks; tightness around the abdomen, loss of appetite, gastric pain and obstinate constipation; dysuria. Knees give way under her. Duration seven years, getting rapidly worse. Rash and sore throat eleven years before.

Examination.—Rombergism, slight ataxia, no hypotonus, absent knee and ankle reflexes, pupils equal, very sluggish to light. Wassermann serum positive; cerebrospinal fluid positive; globulin positive; mononuclear cells 137.

Treatment.—Salvarsan, 0.3 gm., two doses; 0.6 gm, two doses in six weeks. Six months later she was enjoying exceptionally good health, free from pain. Is hyperesthetic around the left side of chest. Constipation severe. Dysuria gone. Paresthesia greatly diminished. No difficulty in walking. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; no cells.

While the object of antisyphilitic treatment is sterilization of the spinal fluid and blood, it will be noted that this was not attained in several of the foregoing cases. This was due chiefly to imperfect cooperation on the part of the patients in returning for treatment. But even when the cooperation is complete and the treatment most vigorous, there is a small percentage of cases in which the Wassermann in the serum is so persistent as to justify the term "Wassermann-fast," as recently applied by Dr. David M. Kaplan,[5] director of the laboratory of the Neurological Institute. The report of one such case will suffice:

Case 14.—The patient is a professional man aged 47, unmarried, who came complaining of incomplete control of his legs, weakness and awkwardness in walking associated with numbness in the peroneal region and a cushion sensation under the ball of the foot, with an occasional pain in the legs. This condition had been remarked during the past four months. He recollected having had an indefinite sore on the penis, to which he paid no attention, which healed spontaneously.

---

[5] Kaplan, D. M.: The "Wassermann-Fast Tabes," The Journal A. M. A., Dec. 20, 1913, p. 2214.

Examination showed a moderate Romberg, unsteadiness of gait, fine tremor of the hands and lips on effort, absent knee and ankle reflexes and very small equal pupils wanting in reaction to light. Tabes being evident, he was given the treatment recorded in Table 1.

Besides the arsenical treatment he has come faithfully every week and received 1 grain of mercury in the form of salicylate intramuscularly for the past forty weeks. He has never missed a day at work during this period except when he was laid up twenty-four hours for lumbar puncture. To-day he is hale and strong, feels exceptionally well and is engaged in a busy professional career. His mind is unclouded, his tremor has disappeared, his walking is above suspicion and his Rombergism is gone. His reflexes at the knee and ankle are still absent and his pupils are smaller than the head of a pin and are immovable to light.

OPTIC-NERVE ATROPHY

Early adverse criticism of results following salvarsan administration made capital of the fact that optic-nerve atrophy was sometimes observed. Faulty technic may have been the cause of such a sequela, but from our observations we are inclined to believe that the optic atrophy was already in process, although perhaps not demonstrable, at the time that the drug was given. For we have seen an incipient optic atrophy the result of syphilitic virus go steadily forward to complete atrophy while under vigorous salvarsan therapy.

Case 15.—O. L. R., man, aged 41, married. Complaint: Pains through the trunk, in the elbows and knees, girdle pains, vesical incontinence, obstinate constipation. Poor control of legs, inability to walk in the dark. Hypotonus. Duration one year; progressive; chancre ten years before.

Examination.—Romberg, Argyll Robertson pupils; diplopia. External strabismus left eye. Slight diffuse pallor each optic disk, visual fields slightly reduced. Knee and ankle reflexes absent, also gone in biceps and triceps. Wassermann serum positive; cerebrospinal fluid positive; globulin weakly positive; mononuclear cells 110.

Treatment.—Neosalvarsan, 0.9 gm., five doses in three months; salvarsan, 0.3 gm., four doses during succeeding nine months. Observation one year later: no pain, no incontinence, but still ataxic. Pallor of optic disks very pronounced, visual fields much reduced, sight almost gone in the left eye. Strabismus still present. Wassermann serum positive; cerebrospinal fluid positive; globulin positive; mononuclear cells 33.

On the other hand, we have observed a progressing optic-nerve atrophy held in check by the use of salvarsan; in fact, vision improved after therapy.

Case 16.—J. D., man, aged 37, married. Complaint: Failing vision for two and a half years, cannot now see to read. Hearing also failing. Sharp, stabbing pains in the legs, at other times cold sensation in the legs; indescribable disagreeable sensation in the abdomen. Chancre 15 years ago. Treated for eight months with mercury and potassium iodid by mouth.

Examination.—Nutrition good, no Romberg, no ataxia, no hypotonus, very little postural disturbance. Knee reflexes diminished, ankle-jerks present. The pupils are equal but irregular and moderately dilated. Reaction to light is almost imperceptible, but good in accommodation. Visual fields reduced. Counts fingers at 4 feet. Fundi show marked optic atrophy. Wassermann serum positive; cerebrospinal fluid positive; globulin positive; mononuclear cells 10.

He developed an acute mania and spent eight weeks in a state hospital. Three months after examination he received three doses of neosalvarsan within ten days. Four months later the physical signs were unchanged. The optic disks still showed an unaltered marked atrophy. He could now count fingers across a room, recognize persons and go about unaided without difficulty. Ten months after treatment, however, vision was definitely failing.

When laying stress on the beneficial results following the use of salvarsan it is well for us to bear in mind the remarkable curative power which Nature alone possesses. A case which emphasizes this point is as follows:

Case 17.—J. Q., man, aged 35, single. Complaint: Lightning pains in the legs, great difficulty in walking, unable to stand alone, difficulty in starting the stream of urine, occasional rectal incontinence, severe abdominal cramps at times and double vision. This condition had developed during the past three years and was now practically stationary. He had had a chancre twenty years before, which was untreated.

Treatment.—This consisted of four months of weekly intramuscular injections of mercury and two injections of salvarsan, six months ago, from which he experienced little relief. One month ago he came down with typhoid fever from which he has just recovered. On examination he is badly emaciated, unable to stand alone, profoundly ataxic, the tendon reflexes are gone and the pupils rigid to light. Wassermann serum negative; cerebrospinal fluid negative; globulin weakly positive; mononuclear cells 28 per cubic millimeter.

Neither the patient's condition nor the reaction of the serum warranted active syphilitic treatment; so he was placed on tonic measures, as massage baths, electricity and such exercise as he was able for. After two months he had gained 30 pounds in weight and was correspondingly stronger. He could stand and walk alone, with moderate ataxia. His pains had ceased, his diplopia, dysuria and rectal incontinence had disappeared. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; cells 3.

Here was a man who had sufficient treatment six months before to render negative his Wassermann reactions without improvement in symptoms, succumbing to an acute infectious disease, during the convalescence from which his cerebrospinal fluid passed from the pathologic to the normal state and his symptoms were vastly ameliorated without antisyphilitic remedy. Considerable theorizing might be done, but the indisputable fact is the remarkable recuperative and reparative power of the body tissues on which we can depend in combating the toxins of syphilis.

Table 2 shows what a striking effect salvarsan and neosalvarsan have on the Wassermann reaction, globulin content and cell-count in the cerebrospinal fluid in tabes dorsalis.

MOTOR-TRACT DISEASE

Turning now from diseases in which the virus of syphilis has wrought greatest havoc on the sensory tracts, let us consider the possibilities in dealing with those whose symptoms are chiefly dependent on disturbance of the motor paths. While the disabling of motor paths, for example, ptosis or diplopia, is in the majority of instances the first symptom that strikingly calls the patient's attention to the late effects of syphilis, there can be little doubt that the earliest inroads are made on the sensory tracts. It is usually possible to elicit from an intelligent patient the appearance of subjective sensory disturbances previous to the occurrence of motor symptoms. This opinion, which is now held by most neurologists, has recently been reaffirmed by Holmes[6] in an article on tabes.

In those cases, fortunately relatively fewer, in which the motor system bears the brunt of the attack of the virus of syphilis, the results of antisyphilitic therapy are usually less fortunate than those obtained in disease of the sensory system. There is apparently no means of prognosticating the result either from the clinical picture or from the Wassermann reaction, especially when the myelitis produces a spastic paraplegia or an Erb paralysis. Paralyses resulting from involvement of the third, fourth or sixth cranial nerve *yield more readily to salvarsan, especially if of recent* origin. Although the results of many of the spastic paraplegias due to syphilis are not all that we could wish, there is a sufficient number of recoveries which approximate the normal to justify pushing this form of therapy in all such cases at least to the point of rendering the reaction negative. As examples of this class, the reports of two similar cases follow. One patient recovered, the other *did not*.

Case 18.—E. F., woman, aged 36, married. Complaint: Unable to walk or stand; absolutely no control of bowels or bladder, diplopia on looking downward, cord-like tightness around the abdomen. Duration eleven weeks. No knowledge of infection. Two children died in first year of life, three living.

Examination.—Cannot stand, cannot move her lower extremities at all as she lies in bed; entirely incontinent. moderate incoordination of both upper extremities. Knee and ankle reflexes plus, double Babinski, double ankle clonus, abdominal and epigastric reflexes absent, normal in the arms; left palpebral aperture narrowed, eye turns slightly outward in looking down. Right pupil rigid to light, left small but responds. Fundi normal. Belt of hypesthesia from sixth to twelfth dorsal segment distribution. Wassermann serum negative; cerebrospinal fluid negative; globulin positive; mononuclear cells 80.

Treatment.—Neosalvarsan, 0.9 gm., every second day for four doses, and massage. Four weeks later neosalvarsan, 0.9 gm., two doses within a week. Fifteen months later patient had gained 40 pounds in weight, going about doing the housework; walks without support with slight wavering, but securely; has no incontinence, no diplopia, no pain, no paresthesia.

---

[6] Holmes, Gordon: The Diagnosis of Tabes Dorsalis, Brit. Med. Jour., March 14, 1914, p. 573.

Examination.—This reveals the tendon reflexes still plus, double Babinski, left exhaustible ankle clonus. Pupils unchanged. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; no cells.

Case 19.—W. S., man, aged 41, married. Complaint: Legs are weak and shaky; legs jerk up in bed; pain about the waist; impotent; not incontinent. Duration six months, much worse recently. Chancre fourteen years ago, also secondary rash. Treatment for three years with mercury and iodid.

Examination.—Sways in Romberg position; walks stiff leggedly scraping toes; knee reflexes plus; double ankle and patellar clonus; double Babinski; epigastric reflexes absent; abdominals and cremasterics sluggish; pupils unequal but respond to light and accommodation. No demonstrable sensory disturbance. Mental examination negative. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; mononuclear cells 103.

Treatment.—Neosalvarsan, 0.9 gm., four doses a week apart. Three months later neosalvarsan, 0.9 gm., three doses in three weeks. Seventeen months later patient is still markedly spastic in his gait and the physical signs if changed are more pronounced. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; no cells.

These two cases exhibit the capriciousness of results in treating syphilitic diseases of the motor tracts. If inclined to offer a favorable prognosis, one would probably have selected the case with the active exudative reaction in the central nervous system.

This type of case, which is almost an entity in itself, usually offers the most stubborn resistance to treatment, and in that respect differs radically from the usual forms of cerebrospinal syphilis.

CEREBROSPINAL SYPHILIS

The rapidity with which the ordinary types of cerebrospinal syphilis, including meningo-encephalitis and meningomyelitis, respond to salvarsan is very gratifying. Headaches, somatic pains, mild palsies, paresthesias, sluggish motor responses and similar manifestations, as a usual thing, yield in a comparatively short time to treatment with salvarsan. A few examples are more eloquent than much comment. Suffice it to say that similar results could not be accomplished without months of treatment, if at all, under mercurial therapy.

Case 20.—P. H., man, aged 35, widower. Complaint: Inability to work because of stiffness in the left knee, which disappears to a degree after working it back and forth; lack of prompt response in movements of the left foot; catching of the heel on the ground; difficulty in going up and down stairs; "creeping feeling" in the left hand and elbow. Duration two years, getting worse. Chancre two and one-half years previous.

Examination.—Station normal, no noticeable defect in gait, fine tremor of the hands. Knee and ankle reflexes exaggerated, left more than the right. Babinski on the left, left ankle and patellar clonus, left epigastric and abdominal reflexes diminished right plus, pupils equal and respond promptly to light. Wassermann serum positive; fluid negative; globulin positive; mononuclear cells 26.

Treatment.—Salvarsan, 0.6 gm., three doses about a month apart. Two months after the last treatment patient was working steadily as an inspector of plumbing and had no difficulty or complaint of any description, except a slight stiffness of the left knee on arising. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; no cells.

Case 21.—N. V., man, aged 30, single. Complaint: Dizziness, intermittent headache, vomiting in the morning, nausea during the day, feeling of uncertainty when on his feet, occasional blurring of vision, pain in the stomach. Duration four months, steadily worse. Chancre six years before.

Examination.—Station and gait normal, occasional general tremor, slight occasional choreiform movement of shoulders and arms, reflexes sluggish; on reinforcement the right knee-reflex is greater than the left; right ankle-jerk present, left absent; right pupil reacts to light; old scar on left cornea due to trauma; vision of right eye normal. Wassermann serum positive; cerebrospinal fluid positive; globulin positive; mononuclear cells 915.

Treatment.—Salvarsan, 0.6 gm., three doses a week apart. One month after last injection his symptoms had entirely disappeared. Wassermann serum positive; globulin negative; cells 30.

He then received weekly injections of 10 minims of salicylate of mercury intramuscularly and after two months was still quite well. Wassermann serum negative; cerebrospinal fluid negative; globulin negative; cells 13. The tremor and the jerky movements have disappeared. Reflexes remain the same.

Case 22.—W. K., man, aged 26, single. Complaint: Headache; insomnia; twitching of the left side of the mouth, left shoulder and left side of the body; occasional vomiting; completely unable to speak four days ago. Duration three months; progressive. Chancre four months ago.

Examination.—Very slight paresis of right facial nerve, reflexes all present and equal, pupils equal, not quite round, respond promptly to light and in accommodation; station, gait and remainder of physical examination normal.

Mental examination showed marked defects in orientation, memory and attention. Speech somewhat indistinct. Wassermann serum positive; cerebrospinal fluid positive; globulin positive; mononuclear cells 533, polynuclear cells 13.

Treatment.—Neosalvarsan, 0.9 gm., five doses within three weeks. Two months later neosalvarsan, 0.9 gm., two doses three days apart. At the end of that time, ten weeks after the initial examination, no physical abnormality and his mentality has cleared entirely. No speech disorder. Wassermann serum negative; cerebrospinal fluid negative; globulin positive; mononuclear cells 16.

SYPHILITIC MASS FORMATION

Gummata of the brain, cord or meninges are much less common than was formerly supposed. Modern laboratory and therapeutic methods have disclosed the fact that conditions which would formerly, doubtless, have been diagnosed as gumma, must come under the head of cerebrospinal syphilis with a pronounced cellular exudate. This may take the form of a meningo-encephalitis or meningomyelitis giving rise to localized symptoms. The rarity of cases in which a diagnosis of gumma in the central nervous system is beyond the pale of dispute makes our experience with salvarsan in their treatment too inconsiderable to be of value in drawing conclusions.

NEURASTHENIC TYPE

There is still another class of syphilitic cases in which the patients show no gross lesion of the nervous system or other viscera, but complain of vague inconstant neurasthenic symptoms which are often called functional.

Many such, beyond doubt, have been treated as functional or neurasthenic even by the ablest hands. In such cases, when there is no knowledge of infection, one is justified in making a therapeutic test on the evidence furnished by a Wassermann reaction repeatedly positive. These cases are rather more frequent than one would suspect, and after observing the relief which comes to the patients after their blood has been sterilized by salvarsan, one regrets that not all neurasthenics can be so definitely and promptly cured.

INHERITED SYPHILITIC NERVOUS DISEASE

We have yet to appreciate fully the ultimate effects of syphilis on the offspring. Doubtless a considerable percentage of the hosts of mentally backward children have had their central nervous systems impaired *in utero* by the vicious toxins of the *Spirochaeta pallida*. We have under treatment a number of such children exhibiting positive Wassermann reactions, but the time is not yet ripe for an expression of opinion as to the value of therapy.

Another dreadful manifestation of syphilis in the parent is epilepsy in the child. By this is not meant the jacksonian movements which may characterize cerebrospinal syphilis in the exudative stage, but generalized convulsions in a child whose cerebrospinal fluid is normal, but whose blood and that of the mother returns a positive Wassermann. Such cases are comparatively rare, and it is very difficult to make the Wassermann reaction negative. Under salvarsan treatment the number of attacks becomes greatly diminished and in some instances ceases altogether.

GENERAL PARESIS

The tendency of the *Spirochaeta pallida* to lodge in hordes in the non-vascular regions of the cerebral cortex does not augur particularly well for the treatment of general paresis. It is not surprising, then, that the percentage of cures and even cases of arrested progress is very small. Not infrequently a case of paresis will show improvement under salvarsan treatment for a greater or less period, but eventually exhibit progressive deterioration. In this condition the Wassermann reaction in the serum and spinal fluid is extremely resistant and in only a comparatively few cases have we been able to influence it permanently. We can but devoutly hope that the method of subdural salvarsan therapy employed by Swift and Ellis[7] may be a boon to the general paretic. But inasmuch as it has been demonstrated by Kramer[8] that the subdural space around the cerebral cortex is not continuous with that below the tentorium cerebelli and around the spinal cord, any fluid introduced into the subdural space around the cord will not arrive at the cerebral cortex except by way of the central canal of the cord and the ventricle, or after being taken up by the general vascular system. The outlook is therefore not encouraging. The report of a case in which the deteriorating process was arrested may prove interesting:

Case 23.—W. M., man, aged 31, single. Complaint (by his mother): Memory failing; low-spirited, irritable; unable to remain at one task; shaking of the hands; speaks so indistinctly that he can with difficulty be understood. Patient states that he talks as well as he ever did and "feels fine." Duration six weeks; progressive. Chancre seven years before with rash and sore throat.

Examination.—Station secure, gait hesitating; marked tremor of the lips, tongue and hands; no hypotonus, slight incoordination; absent knee- and ankle-jerks; plantar flexion, plus abdominal, epigastric and cremasteric reflexes; unequal pupils, rigid to light; tremulous, hesitating speech; sits alone in a depressed attitude; when he is addressed smiles blandly and says he "feels fine." When aroused ascends into a euphoric state; insight fair, memory, orientation and attention good. The treatment and its effect on the Wassermann reaction are given in Table 3.

To-day he is a pleasant, agreeable, rather jovial person, with good sense of humor and of normal conduct. He is a constant reader and relates the details of a story which he has read. His memory and insight are excellent. His attention is good but in the midst of a complexity of duties he becomes easily excited. Gaged by the Binet-Simon tests his mental age is 12 years. His tremors have disappeared and his speech, though slightly hesitating, is clear and distinct. Pupils and reflexes remain unchanged. Although he has not attempted to resume his work as a stenographer, he is industrious about the care of his house and grounds.

From Table 4 is evident the high resistance of the Wassermann reaction both in the serum and in the cerebrospinal fluid in the majority of cases of general paresis.

THE PROVOCATIVE DOSE

Certain persons seem to arrive at such a state of tolerance for the syphilitic parasite that the tissues no longer give chemical evidence of active resistance to the invader. Salvarsan is often of value in arousing the latent capabilities of the body-cells and may be employed to advantage in the doubtful cases as a diagnostic measure. Untreated cases with suspicious symptoms, which are luetic, presenting a negative Wassermann reaction, may have this changed to a positive reaction by a single small injection of salvarsan. The blood should be drawn from one to three days after the injection.

PLAN OF THERAPY

While salvarsan has proved our most rapid and most efficient agent in treating syphilitic nervous disease, the use of mercury, preferably intramuscularly, in the interval between doses of salvarsan, has proved highly desirable. The salicylate in a purified petroleum oil suspension has been chiefly employed by us.

It is probable that the intermittent treatment will prove advantageous. By this is meant a succession of periods of treatment and periods of rest, each covering a number of weeks. The spirochete is thus not rendered immune or less sensitive to the specific therapy as may occur when treatment is continuous. The great drawback to this plan is losing sight of the patient, whose interest may wane.

In our enthusiasm in attempting to render the Wassermann reaction negative, we must not forget that we are treating the patient, not the condition of his serum. Besides the directly antisyphilitic remedies, all adjuvant measures possible must be employed, including systematic exercise in the open air, Fränkel exercises when necessary, tonic baths, various forms of electricity, massage, the cautery when indicated and a simple nutritive diet. But in observing the progress of therapy and the decadence of the syphilitic process, the Wassermann reaction and the cell count are our most enlightening guides, and without them we are in the dark. Improvement in symptoms nearly always follows *pari passu* with improvement in this.

---

[7] Swift and Ellis: New York Med. Jour., 1912, xcvi, 53.
[8] Kramer: New York Med. Jour., March 16, 1912.

From a continuous study and review of the work of the past four years we submit the following conclusions, which differ in no essential from those expressed in a report by this service on the same subject two years ago.[9]

CONCLUSIONS

1. The treatment of syphilitic nervous diseases without the Wassermann reaction and spinal fluid analysis is guess-work.
2. The nervous system may be the site of attack within a few weeks after the initial lesion appears.
3. The earlier antisyphilitic treatment is instituted in syphilitic nervous diseases, the greater the probability of complete recovery.
4. Salvarsan is the most potent remedy in our armamentarium in the treatment of syphilis of the nervous system.
5. Salvarsan is not all-sufficient.
6. One or two doses are not usually sufficient to effect a cure, but may check the disease for a time.
7. Syphilitic nervous diseases improve most when salvarsan therapy is combined with mercurial treatment and general tonic measures.
8. Therapy should be continued until the serology is negative if possible.
9. The serology should be examined periodically after a negative status has been achieved.

CASE OF POISONING BY SCOPOLAMIN (HYOSCIN) HYPOBROMATE

Mervin Tubman Sudler, Ph.D., M.D., Rosedale, Kan.
Associate Dean and Professor of Surgery, University of Kansas School of Medicine

May 28, 1913, in the forenoon, W. R. P., man, aged 21, consulted an oculist, who discovered that he had no homatropin to use in the examination. Calling by telephone a local drug-store, he ordered some powders, each to contain ½ grain of homatropin. The messenger appeared shortly with an envelope containing the supposed powders of homatropin. The oculist immediately made a solution by dissolving one of the powders in thirty drops of distilled water (a method used by him for obtaining approximately 1 c.c.), omitting to read the label, which was small and inconspicuous. The label read "hyoscin hypobromate, grs. ½." The patient then lay on a couch and 3 drops of the solution were dropped in each eye, so that about 1/10 grain of scopolamin (hyoscin) hypobromate was administered in this way. In a few minutes he complained of dizziness. While he managed to stagger to a chair, he immediately threw himself back on the couch on account of his sensation of dizziness and faintness. His pulse at this time was beating at the rate of 150 a minute, and at times it was too indistinct to be counted. He was actively delirious, having delusions of playing baseball—from his conversation apparently with much interest. He was closely watched and received 1/30 grain of strychnin hypodermically. No other medication was employed. His condition gradually improved, so that by 4:30 o'clock his pulse was reduced to 110 and was stronger. He was then removed to the hospital. He was still delirious and seemed to realize that he was talking irrationally, but said that he was unable to control it. By 7 o'clock his pulse was 86, his respiration 18, his temperature 99.4, and he was practically rational. On the following day, at which time I first saw him, his pulse varied from 60 to 86 and his temperature reached 99.2. No trace of his mental confusion remained. He left the hospital on the third day. While he has worried somewhat about himself since the occurrence, there is no evidence that any permanent injury has resulted from his large dose of scopolamin hypobromate.

Early Specialization.—The Egyptians were right in neglecting the general calling of a physician and of dividing the profession.—Montaigne.

REPORT OF A CASE OF PELLAGRA WITH LATE SKIN LESIONS

Thompson Frazer, M.D., Asheville, N. C.

It has been frequently observed that the skin-lesions of pellagra, although having given the disease its name, are by no means necessarily, or even commonly, the first symptoms to appear. It is perhaps less generally known that symptoms referable to other organs may persist for such a long period without the development of the dermatitis that one may be entirely put off the scent if one depends on this symptom alone. I cannot better lay stress on this feature of pellagra than by briefly reporting a case recently seen by me in which the late appearance of the skin-symptoms was no less than tragic.

Mrs. X., a woman of 30, living in a neighboring mountain town, married and the mother of five children, had always been well until shortly after the birth of the last one, a seven-months' child, born July 1, 1913, and living only a few days. The puerperium presented no unusual features and the patient remained well until about a month after delivery. About this time she noted that her strength was not quite up to par, and the appetite, hitherto good, became capricious and soon vanished almost completely. Associated symptoms were an intense nausea, with vomiting, repeated several times daily, and persisting for three or four months. Pain and burning in the stomach were early and distressing symptoms. Following in the wake of these "dyspeptic" symptoms, there appeared a diarrhea, at first mild, but soon attaining considerable proportions. The diarrhea, with movements varying from ten to twenty daily, persisted until March, 1914. The patient, as a result of this drain, became weaker and weaker, yet still attempted to keep about and to attend to her household duties. During this period she was seen by several physicians and was treated by them for "stomach-trouble," "intestinal catarrh" and "consumption of the bowels," with but little improvement. About the middle of March, 1914, the patient became more acutely ill, suffering with extreme nervousness, a recurrence of the vomiting, severe burning in the stomach, and a sore mouth and tongue, accompanied with profuse salivation. She was so sick that she was compelled to take to her bed. At the same time there appeared on the backs of the hands and forearms a symmetrical erythema resembling sunburn, which blistered and later scaled. The patient has been in bed continuously since the acute attack.

I saw her for the first time, May 15, 1914. In the course of the two months which she has spent in bed the diarrhea has improved so that she has only two movements daily, the nausea and vomiting have disappeared and the appetite has partly returned. The chief complaints are the burning pain in the feet and the cramps in the calves of the legs, both so severe that she is unable to get much sleep, the loss of which adds greatly to her already exhausted condition. While the sore mouth has improved, the salivation is profuse and the patient is almost continuously wiping the saliva from the lips and chin, which have become excoriated as a result of the constant discharge. On the backs of the hands and forearms is a symmetrical, rather sharply defined dermatitis, with scaling still going on. Both elbows are ichthyotic in their roughness. Emaciation is extreme; the eyeballs are sunken in their sockets; the face is drawn, the expression set and anxious, while speech is slow and attended with much difficulty on account of both the salivation and the mental and physical exhaustion. Sleeplessness, made worse by pains in the legs and feet, has intensified the prostration to such a degree that the patient is unable to sit up in bed without fainting. Mental symptoms, such as loss of memory and "flightiness," are present, but the patient makes the attempt to appear cheerful in spite of the feeling of apprehension which she is unable to throw off.

The main features of the case, then, are as follows: Here is a woman evidently suffering with pellagra, confined to bed for over two months, and requiring the constant attendance of a nurse, so extreme is the prostration. And yet for over seven months prior to the advent of the dermatitis and other frankly pellagrous symptoms, there was nothing in her history which even remotely suggested pellagra to the physicians in charge of the case, so that the patient was allowed to be about and had greatly exhausted her strength before pellagra showed itself in its true colors. The lesson to be learned from this case is that the physician must not wait for the dermatitis before suspecting, at least, the existence of pellagra; and an evident corollary is that in pellagrous areas a long-continued attack of "stomach and bowel trouble" must be regarded as cause for alarm. It is hoped that this brief case-report will bring out the point which I wish to emphasize, namely, that pellagra may exist for a long period—months and possibly years—before the characteristic dermatitis makes its appearance. In this instance it was probably the pregnant state which awoke a latent pellagra, and the premature birth was in all probability the result of pellagrous infection.

Therapeutics

TETANUS

Statistics are constantly impressing us with the facts: (1) that tetanus is preventable; (2) that frequently it can be stopped after it has developed; (3) that it may be cured after it has become well established. Consequently, it should never be considered absolutely incurable.

PREVENTIVE TREATMENT

The most successful preventive treatment and practically the only successful one after the disease has developed is by tetanus antitoxin. As a preventive, this antitoxin ranks even ahead of diphtheria antitoxin; therapeutically, it is far inferior, because part of the toxin produced by the tetanus bacilli forms a combination with the nerve-cells of the spinal cord. The greater portion of the toxin seems to circulate in the blood, but a small part is absorbed by way of the lymph-vessels and passes to the spinal cord by means of the nerve trunks.

One of the greatest dangers from this terrible infection is that the local lesion *may not* show signs of disturbance when the central nervous system suddenly gives indications of poisoning. The kinds of wounds likely to contain the tetanus bacillus, however, are positively known. These are: all wounds that may contain dirt contaminated by manure, such as that from streets, stables or barns and even fields; wounds by firecrackers; by gunshots, especially with blank cartridges; by crushing, in machinery or otherwise. The feet and hands are especially prone to be infected with tetanus germs. Street injuries that are not deep or perforating, but grinding and lacerating, are very likely to cause tetanus infection. Also, it has been stated that tetanus bacilli may be harbored in an old injury, yet cause no symptoms until some other injury or general disturbance of the body has caused the normal protection against infection to be broken down; then toxins from the bacilli may be absorbed and tetanic symptoms develop. This would account for some otherwise apparently unaccountable developments of tetanus.

DRESSING THE WOUND

The corollary to the preceding statement is that in every case of injury, whenever the wound may have been contaminated by street dirt or by objects that have been exposed to street or barn dust, first, all foreign matter should be removed from the wound, even if to do so it becomes necessary to cut down on a penetrating wound under anesthesia; secondly, not the open wound alone, but the surrounding tissues as well should be painted with tincture of iodin, then the wound should be dressed with some antiseptic dressing, of which a strong alcohol wet dressing is, perhaps, as good as any; thirdly, the patient should be given immediately an injection of 1,500 units of tetanus antitoxin.

Various antiseptic soaps, washes and solutions have been and may be used in cleansing the wound and dressing the injured part. It should be remembered that, if the tincture of iodin is used, its germicidal action is greater the drier the parts are and the less they have been bathed with solutions.

It should be emphasized that statistics, from both Europe and the United States, compiled from repeated observations by careful surgeons and clinicians, indicate that it is almost inexcusable not to give a patient, who has suffered one of the above-mentioned injuries, or who has been known to have had an injured part contaminated with a possibly infected dirt, the preventive dose of tetanus antitoxin.

Antitetanic powders have been prepared with antiseptics, and although, experimentally, their use has been successful in preventing the development or absorption of tetanus toxins, still it has not been shown that the results were not accidentally successful because of the strong antiseptic that was combined with the antitoxin powder. It might, however, be well to apply antitetanic serum to the open wound at the same time that the preventive subcutaneous injection is given.

According to investigations, the immunity caused by the antitetanic injection does not seem to last more than from two to three weeks, but this is generally long enough to prevent the development of the infection from any particular injury.

ANAPHYLACTIC SYMPTOMS

The usual reaction which takes place from the injection of any horse-serum may occur, that is, anaphylactic symptoms, but these are rarely severe, and are shown mostly by slightly increased temperature, and light urticarial eruptions with some itching. When a number of injections must be made in the treatment of tetanus, there is, of course, sooner or later, greater liability of serum reaction. In some instances it has been found that hypodermatic injections of atropin sulphate have prevented some of the symptoms.[1] As atropin alone may cause, through irritation of the skin, a scarlatiniform eruption, it seems rather surprising to find atropin successful in preventing symptoms of anaphylaxis. It should be remembered that, in hay-fever or asthmatic patients, as serious poisoning may occur with this horse-serum as in the use of diphtheria antitoxin. Therefore, before using antitetanic serum as a preventive of the disease, it should be carefully ascertained whether or not the patient is susceptible to horse emanations.

If the first symptoms of tetanus are in evidence, that is, if the disease is about to develop, or has developed, it may be aborted by the immediate injection of from 5,000 to 10,000 units of antitetanic serum, best administered intravenously. It may also be well, within a few hours, to give in addition 5,000 units subcutaneously. If the symptoms are well developed, or the patient shows severe poisoning, from 10,000 to 20,000 units should be immediately given intravenously, and in ten or twelve hours 3,000 to 5,000 units subcutaneously, provided the symptoms have not markedly ameliorated. In twenty-four hours the same subcutaneous dose may be repeated. A more effective treatment, however, is gently to inject 5,000 units into the spinal canal, if the intravenous injection has not ameliorated the symptoms in a few hours. This seems to be the most effective means of combating the action of the toxins on the spinal nerve-cells. In fact, it has been proved that the toxin in these nerve-cells cannot well be combated by antitoxin in the blood-stream, but that it can be when the antitoxin is injected into the spinal canal.[2]

Even if the symptoms have markedly ameliorated, if any signs such as muscle stiffening, show that the disease is continuing, a smaller injection may be given subcutaneously once or twice in twenty-four hours for several days.

DOSAGE OF ANTITOXIN

The amount of the antitoxin that may be used without causing harmful symptoms seems to be without any narrow limit; several thousand units may be administered every few hours, if it seems advisable, and 20,000 to 30,000 units intravenously. Many thousand units may be given during the course of the disease with only good results.

Finally, each physician and surgeon should seriously consider the advisability either of using a prophylactic dose of tetanus antitoxin serum in every injury of the character described; or, if his patient, or the patient's family refuses to allow such an injection to be given, of securing a signed release from responsibility or blame should tetanus later develop.

Jan. 13, 1912, p. 104.

[2] See The Serum Treatment of Tetanus, editorial, The Journal A. M. A., April 11, 1914, p. 1174.

Carious Teeth.—Statistics of the London County Council show percentages of carious teeth among schoolchildren are as follows: Entrants (that is, very young children), boys 10.3, girls 10.1; children between 8 and 9, boys 17, girls 16.5; between 11 and 12, boys 12.9, girls 11.8. The increase during what may be described middle school age is ascribed to the fact that the milk-teeth are then being changed for the permanent. An attempt is made to classify the percentages of bad teeth according to social condition. About 39 per cent. of the children from well-to-do homes have defective teeth, as against 27 per cent. from very poor homes. This is accounted for by the fact that the coarser food eaten by the poorer children gives their teeth more work, and hence keeps them clean and strong. It is also suggested that the poor are able to give their children fewer sweets, and only those of the cheap or boiled-sugar variety. These sweets break up clean in the mouth, whereas the caramels and chocolates eaten by better-off boys and girls tend to cling round the teeth and form a nidus of fermentation. Writing on this subject, Dr. Sims Wallace, late dental surgeon to the London Hospital, states that there are in this country about 21,000,000 teeth in a state of ruin through eating sweets, and urges the adoption of a diet containing farinaceous food in a form which will stimulate mastication, as brown bread, and also the eating of fresh fruit at the conclusion of a meal. By means of the fruit the teeth are cleansed. The best fruit for this purpose is probably the apple, which, if eaten at the end of a meal, leaves the mouth fresh and physiologically clean.

THE TRANSMISSION OF TYPHUS FEVER

In September, 1909, Nicolle, Comte and Conseil[1] reported the successful transmission of typhus fever from one monkey to two others by means of the bite of the body-louse (*Pediculus vestimenti*). In their report they showed that body-lice that had fed on an infected monkey were able to convey typhus fever some time between the first and the seventh day thereafter.

Independently of Nicolle and his co-workers, Anderson and Goldberger,[2] in their studies on typhus fever in Mexico in November, 1909, reported two attempts to transmit Mexican typhus from man to the monkey by means of the bite of the body-louse. In one of their experiments the monkey showed a slight elevation of temperature eight days after the last exposure to the bites of the infected lice, but they stated that circumstances made it impossible to test the immunity of this animal. In view of later studies by them and by others, they concluded that it was very probable that the elevation of temperature was due to infection with typhus.

Ricketts and Wilder,[3] also working on the Mexican typhus, reported in 1910 that they were able to transmit the virus of typhus fever by means of the bite of the body-louse from man to monkey and from monkey to monkey. They also reported the successful transmission of the typhus virus to the monkey by introducing into scarifications of the skin the abdominal contents of infected lice. They stated that, as a rule, in their louse experiments, the monkeys had no very significant temperature reaction and that proof of infection was dependent on immunity tests with virulent blood.

In 1911, Nicolle and Conseil,[4] continuing their work of two years previously, reported further successful experiments on the transmission of typhus to the monkey by means of the bite of infected body-lice.

Subsequently, in 1912, Anderson and Goldberger,[5] continuing their work on typhus in both the United States and Mexico, reported the successful transmission of both the Mexican and New York typhus by means of infected lice. They also reported the first evidence incriminating the head-louse (*Pediculus capitis*) as a possible agent in the transmission of typhus.

All the work above referred to on the transmission of typhus fever by means of the louse has been on the transmission of the disease to the monkey by means of body-lice that had fed either on infected monkeys or on human beings, and until recently no exact experiments had been reported on the transmission of the disease from man to man by means of the bite of infected lice. There are a number of instances in the literature which strongly suggest this possibility, but the evidence has not been conclusive. Sergent, Foley and Vialatte,[6] however, have recently reported the successful transmission of typhus to man and to the monkey by means of the body-louse and possibly also by means of the eggs from infected lice.

In one of their experiments about two hundred infected body-lice were allowed to feed daily on the authors and individuals who volunteered for this service. On the fourteenth day after the beginning of the feeding one of the subjects developed typhus fever. Lice taken from the individual, after being made into an emulsion, were used to inoculate a monkey which, after four days' incubation, developed typhus. Blood was drawn from this animal and used for the inoculation of a second monkey which, after an incubation period of seven days, developed typhus fever.

Sergent and his co-workers conclude that the mere bite of infected adult lice is sufficient to transmit typhus fever to man and that lice taken from a person so infected are infective for the monkey, by either subcutaneous or intraperitoneal inoculation of an emulsion of the ground-up lice. They maintain also that the inoculation of the eggs from infected lice will produce typhus fever when inoculated into man by slight scarification of the skin.

These experiments of Sergent seem conclusively to settle, by means of experiments on man, the rôle of the body-louse in the transmission of typhus fever. It is a matter of sincere congratulation that much of the recent advance in our knowledge of this once dreaded disease have been due to the work of American investigators, although the toll through the loss of life of two of the investigators — Ricketts and Goldberger — has been severe.

COLLEGIATE ATHLETIC SPORTS

One of the numerous criticisms aimed at college athletics, as practiced among most student bodies at present, relates to their failure to take into account the subsequent needs of the persons involved. To an unbiased observer it cannot fail to appear incongruous that a student should devote months or years to a peculiar sort of physical training, avowedly intended to improve his body and promote his physical well-being, only to find himself, on leaving the university, without any form of exercise or healthful recreation that can be followed during after-college life. Certainly the football hero or the member of the winning crew who has developed himself by special efforts into a muscular giant will find little chance to continue his training after graduation. The reaction from the physical stress of severe competitive intercollegiate athletics to the physical passivity of a sedentary occupation in the counting-house or the law chambers is one of the real hardships to which young men are yearly being inevitably consigned by the inconsistent and improper application in American colleges of a pernicious system of athletic rivalry that ought to be confined to professional athletes.

Wherein competitive sports, in their present abuse, fail to play the wholesome rôle that systematic bodily exercise and legitimate athletic performance should take in the life of young people has been discussed in THE JOURNAL.[1] In several respects our contentions are in accord with the findings and suggestions of a committee appointed by the National Collegiate Athletic Association to report on the encouragement of intracollegiate and recreative sports. As an outgrowth of the feeling that the present methods do not reach the mass of our students, and do not provide them with practical means for exercise and recreation in after-life, Drs. H. Shindle Wingert of the Ohio State University, Raymond G. Clapp of the University of Nebraska, and Charles E. Hammett of Northwestern University have made an investigation of the practices prevailing in one hundred and fifty collegiate institutions representative of all sizes, locations and degrees of athletic prominence. The undue prominence of the intercollegiate, that is, strenuously competitive, type of games is plainly emphasized. Among the 111,000 students of the institutions under consideration, 18,000 are associated with varsity teams as members or substitutes. From the vagueness of some reports, a definite statement cannot be made as to the number who take part in intramural games, but it appears to be about three times as many as in intercollegiate games. The money expended on intercollegiate sports in 150 colleges is reported as $1,090,000. In some cases, the amount reported is said to include expenditures also for intramural sports, the proportion not being given. This fact reduces somewhat the expenditure above indicated for intercollegiate sports, and makes it impossible to give the exact amount spent for intracollegiate activities. A reasonable inference, however, from the facts submitted would be that not one-tenth as much is spent for intramural as for intercollegiate games.

Despite the fact that the actual numbers participating in intracollegiate sports is about three times greater than those of the more conspicuous group of selected athletes, it is very clear to one who studies the returns from the colleges that only a small fraction of the *money spent on intercollegiate games is used to promote* general student athletic activities. Surely if the money of the athletic treasury is to be expended for the physical welfare of the general student body rather than for the staging of a few exciting contests which arouse partisan enthusiasm instead of promoting the physique of the great majority of those concerned, the contribution to the athletic "show" seems unduly prominent. It appears that on intercollegiate sports the large institutions spend the most money per athlete (about $60), but the least per student (about $8), the figures for the medium-sized institutions and the small institutions being respectively $50 and $40 per athlete, and $12 and $13 per student.

After making due allowance for the necessarily approximate character of the reports, the committee is convinced that not more than 50 per cent. of the students in college engage in any form of systematic or organized exercise. It feels, moreover, though it has no way of determining to what extent, that 50 per cent. is decidedly too high a proportion. The committee calls attention to the necessarily unsystematic and sporadic character of the exercises as participated in by the non-university students. Exercise in any form can be of little value unless taken systematically and regularly. Out of 143 colleges, 53, or 37 per cent., are doing nothing to foster and encourage the types of physical exercise and healthful recreation that the student is likely to use in after-college life; 53 per cent. try to create a love of sport by using different games, such as baseball, handball, volley ball, tennis and golf; 21 per cent. give corrective exercises; 14 per cent. give hygienic lectures; 5 per cent. require swimming; 5 per cent. have "hikes," and two colleges teach dancing.

The experts of the National Collegiate Athletic Association believe that intracollegiate sport and recreation should be planned with the constant purpose in view of usefulness in after-life. They are inclined to believe that the conditions revealed by their investigations are due primarily to the lack of appreciation by college authorities and faculties of the vital need of systematic organized instruction in intracollegiate and recreational sports and hygiene. We are impelled, however, to believe that it is not so much the indifference of collegiate authorities as the dominance of competitive intercollegiate athletics which is responsible for the relative indifference to physical exercise in the very communities in which its value is being taught by lectures and text-books. The glorification of an overtrained few means their sacrifice in many instances and the diversion of interest from more wholesome but less spectacular sports. As the committee referred to has concluded, the student should be furnished with such ideas of rational exercise and hygiene as will enable him to adapt his habits of exercise and modes of living to changing conditions in after-life; that is, he should be trained to think and act of his own initiative in these matters. Some games and exercises can be participated in as intracollegiate sports and can be continued in after-life. Tennis appeals to great numbers in everyday life, but only 65 per cent. of the colleges afford the comparatively inexpensive equipment of courts. Baseball requires little equipment; every fairly well-equipped gymnasium can have a swimming pool and each student should be taught to swim. Social dancing and bowling are especially fitted to the opportunities of after-life. Fencing, wrestling, boxing, Indian club exercises and calisthenics, if made interesting and rightly taught, are of substantial value after college; walking and "hiking" can always be indulged in. A period of reconstruction in the whole domain of collegiate athletics is approaching.

THE HEMOLYMPH-GLANDS

For many years various glandular structures have been classed together as lymphatic tissues, in the belief that they are essentially and fundamentally related to each other. The spleen, for example, in many respects resembles a lymphatic gland. Just as in the latter the cellular elements of the tissues are bathed by the lymph which flows through the gland, so in the spleen the blood is poured out into the interstices of the tissue. Thus the malpighian bodies of the spleen are believed to correspond to the follicles of lymph-glands; and it is frequently stated that after splenectomy a compensatory hyperplasia of the other lymph-glands usually occurs. Spleen and lymph-glands alike are assumed to be concerned in the resistance to infection, in the processes of hemolysis and phagocytosis, and in the pathologic hyperplasias and metaplasias.

The name "hemolymph-glands" has been given to another group of related structures about which there has been much difference of opinion. Found in the thoracic and abdominal aggregations of glandular lymphatic structures, they are commonly believed to be specialized to deal with red cells as well as lymphocytes originating in the more typical lymph-glands. In the hemolymph-nodes as ordinarily described, there are found, besides the ordinary lymph follicles, lymph sinuses and blood-vessels, a varying number of sinuses filled with red corpuscles, and Cabot, for example, has stated that in these glands the destruction of red corpuscles, especially in pathologic conditions such as infection and toxemia, is considerable. Whether or not they also take part under pathologic conditions in red cell formation has been disputed.

The general pathology of the hemolymph-nodes has hitherto been regarded as essentially the same as that of the lymphatic glands. Inflammation, syphilis, tuberculosis, the various retrograde changes, and secondary neoplasms are all said to be found in the nodes containing blood-sinuses. Little has been ascertained concerning their special pathology, presumably because of the assumption that no hard and fast line can be drawn between spleen, hemolymph-glands and ordinary lymph-glands. Almost a continuous series of transitional structures has been described, and among them the so-called "accessory spleens" have been depicted as a splenic reticulum so widened as to approximate the blood-sinus of a hemolymph-gland and with the malpighian bodies so diffuse as to resemble the lymphoid portion of the blood-lymph glands. The apparent impossibility of distinguishing in every case between these supposedly interrelated structures has been confirmed through the assertion that hemolymph-nodes can be produced experimentally through the stage of lymph-glands and even back again. The procedures undertaken to secure these changes or the formation of presumably compensatory accessory glands of the hemal type have included the removal of the spleen and injections of toxic substances.

Directly opposed to the foregoing points of view is the contention of a smaller number of investigators, that the true hemolymph-nodes have no connection whatever with the lymphatic system.[1] The solution of the problem is not easy, inasmuch as the lymphatic glands in general—even the peripheral accumulations—are subject to pronounced changes in color and consistency under relatively slight provocation. The histologic examinations to determine assumed changes must be painstaking and the preliminary conditions in some way controlled. In view of the conflicting testimony, Dr. Arthur W. Meyer[2] of the division of anatomy of the Department of Medicine at Leland Stanford, Jr., University has resumed the investigation of the hemal nodes, splenectomy being performed in most cases to provoke the presumed changes. It happens at times that color changes occur in the true lymph-nodes when they become hemorrhagic; but in no instance were hemolymph-nodes formed. As Meyer remarks, changes in lymph-nodes following various influences, of course, have long been recognized; but the nodes remain lymph-nodes and are not converted into hemal nodes having no connection with the lymphatic system.

---

[1] Weidenreich, F.: Ueber Blutlymphdrüsen, Anat. Anz., 1901, xx.

[2] Meyer, A. W.: The Supposed Experimental Production of Hemolymph-Nodes and Accessory Spleens, V. Studies on Hemal Nodes, Jour. Exper. Zoology, 1914, xvi, 241.

If we accept Meyer's conclusions on this subject it is impossible at present to say to what extent the pathologic changes hitherto ascribed to the hemolymph-nodes in disease apply to the glands of the true hemal type rather than to altered lymph-nodes. One can find descriptions of morphologic deviations of the glands of the prevertebral region in cases of pernicious anemia, posthemorrhagic anemia, Banti's disease, leukemia, pseudomelanosis, and in all infections characterized by a general intoxication. But if the hemal nodes are really something actually distinct from the supposedly related lymph-glands, the exact nature of their function and pathology must be ascertained anew.

ACTIVE PRINCIPLES OF ERGOT

Ergot is a parasitic fungus (*Claviceps purpurea*) which grows on rye (*Secale cornutum* or *cereale*) and occasionally on other kinds of grains, more rarely on other plants. Its occurrence on one of the bread-cereal grains explains why it has so frequently given rise to wide-spread epidemics of poisoning and thus acquired a considerable prominence in toxicology. Ergotism due to eating foods prepared from affected rye was very common in the earlier days. It is quite possible for 6 per cent. or more of the fungus to find its way into bread; and less than 1 per cent. is said to be sufficient to produce intoxication. Despite the fact that ergot can readily be recognized, wholesale poisoning from it has been reported even in comparatively recent years. Conspicuous are the epidemics in Nanterre, France, in 1894, in Hungary in 1908, and a long series of calamities in Russia. It may be added that in these cases two different types of symptoms appear with varying frequency, namely, the gangrenous and the convulsive forms, suggesting unlike causative agents.

Aside from these toxicologic features, ergot has long been prominent in therapeutics; and the use of pharmaceutical preparations of it, in particular the fluidextract of ergot, is familiar everywhere. In view of these twofold sources of interest it is not surprising that the composition of ergot should have attracted consideration in the early days of modern chemistry. Though ergot was studied by a number of chemists in the eighteenth century and the earlier part of the nineteenth, the first careful investigation was made by Wiggers in 1831, at a time when the long controversy as to the therapeutic utility of the drug was drawing to a close.[1] Since then there has been a more or less continuous attempt on the part of numerous chemical investigators to unravel the intricacies of a crude product which includes a mixture of stable and unstable compounds of widely unlike character. The number of "active principles" which have been reputed to be present in and isolated from ergot is almost legion. Resins, alkaloids, organic acids and glucosids have been reported. How bewildering the pharmacology of ergot had become a few years ago is indicated by the names of some of the supposed active agents which are still found in all but the most up-to-date literature: ecbolin, ergotin, picrosclerotin, sclerocrystallin, spacelinic acid, cornutin, crysotoxin, secalintoxin, sphacelotoxin, hydro-ergotinin, clavin, ergotinin and ergotoxin.

It is not surprising that in view of this confusion in the domain of chemical analysis on the one hand, and of pharmacologic symptoms and activity on the other, it has been very difficult to decide on a suitable method of assay for pharmaceutical preparations. Nor have matters been helped by the statements that ergot more than a year old is unfit for therapeutic use. Despite the extreme perplexities of the situation, investigations carried out during the past few years have actually resulted in the isolation from ergot of several active principles of undisputed identity and chemical purity, the presence of which adequately accounts for those actions of the drug that have been regarded as especially related to its therapeutic effects, each type of action having been advocated by one observer or another as a basis for its physiologic standardization.

First of these principles is the alkaloid ergotoxin, $C_{35}H_{41}O_6N_5$. Of the physiologic effects described as characteristic of ergot, the ergotoxin carefully investigated by Barger and Dale produces, pharmacologically, in very small dosage, ataxia, dyspnea, salivation, gastro-intestinal irritation, gangrene and the stimulant effect on plain muscular organs — in particular the arteries and the uterus — as well as the subsequent selective sympathetic motor paralysis caused by many ergot preparations. It is apparent from the studies of these investigators at the Wellcome Physiological Research Laboratories in London that many of the earlier "active principles" enumerated above are cruder mixtures of this ergotoxin with inactive substances from the ergot or impurities with a small admixture of the alkaloid.

Barger and Dale pointed out several years ago that the action of pharmacopeial extracts appears too great to be accounted for by the small amount of ergotoxin which they contain, and it seems likely that some other active principle is present in them. It is not difficult to find inactive constituents, such as amino-acids, which are doubtless derived from the metabolism of the fungus. From these, in turn, can be produced products of the activity of micro-organisms among which the amins are a characteristic type. Thus Barger and Dale have discovered hydroxyphenylethylamin, derived from tyrosin, and beta-iminazolylethylamin, derived from histidin by decarboxylation. The former exhibits an energetic vasoconstrictor effect and the latter, even when exhibited in minute doses, calls forth vigorous contractions of the uterus. These are, of course, phenomena characteristic of ergot itself.

---

[1] A summary of this earlier history will be found in the paper by Barger, G., and Dale, H. H.: Ergotoxine and Some Other Constituents of Ergot, Biochem. Jour., 1907, ii, 240.

In addition to those of apparent therapeutic importance, certain other effects have been appreciated. Conspicuous among these is an inhibitor effect on the heart, suggesting an intense, though curiously evanescent muscarin-like action. Finding that the prominence of this effect in the action of different specimens of ergot ran closely parallel with their stimulant action on intestinal muscle, and that both were abolished by atropin, Dr. Dale was led to suspect the presence in ergot of a principle producing both of these responses. This has just been discovered by Ewins[2] to be acetylcholin, a derivative of cholin, which Hunt and de Taveau long ago described as one of the most active bases. There is now no question but that it occurs in the original ergot grains and is not derived from changes incident to the preparation of extracts. Another active principle of ergot, recognizable by its inhibitor action on the heart and its stimulant action on intestinal muscle, has thus been identified. Only the trained organic chemist can adequately appreciate the difficulties and laborious undertakings which have been crowned with this splendid success of the isolation of acetylcholin from a natural product.

THE ETHICS OF EXPERT TESTIMONY

We observe with some concern the tendency on the part of certain men of excellent scientific training and good professional position to forget their responsibility to the public. Utter confusion and misapprehension of scientific aims are likely to be the result in many minds if more discretion is not displayed by some experts in their choice of occasion on which to utilize their technical knowledge in a court of law. There is first of all the effect which the willingness to appear frequently in court is likely to have on the professional reputation of the witness himself. The expert who allows himself to form the habit of accepting any and all offers to "testify" will surely awake some day to find himself involved in a maze of contradictions which will hardly be helpful in maintaining his scientific standing.

An instance of incautious conduct in this respect was afforded in a recent case in Washington, D. C., where the question of milk standards and the interpretation of analyses came to the front. One witness, who holds a high position in a leading Eastern technical school, testified that he "could not say that milk was dirty" unless he "could see actual dirt in the milk." The same witness in a case at Providence, R. I., a few months before (July, 1913), had passed summary judgment on a score of analyses read to him from the records of the United States Department of Agriculture, and had not hesitated to condemn roundly samples of milk on the basis of reported analyses alone. Judgments to the effect that "that is a filthy milk and also a dangerous one," "that contains a large amount of cow manure and intestinal types of bacteria that go along with it," "there is a milk which is undoubtedly from a cow suffering from an udder infection," were pronounced by this witness in Providence when the records of milk analyses, without any other data, were laid before him. In Washington this witness testified that he could not say that milk containing 48,000,000 bacteria per cubic centimeter was either decomposed or filthy. In Providence he declared of a milk containing 20,000,000 bacteria per cubic centimeter that "the chief thing that can be said against the milk is that it is dirty and old; that is probably enough to say against it." In Providence, in July, the presence of the *Bacillus coli* type in milk indicated to this witness the presence of cow manure; in Washington in the following March he answered in the negative the question whether or not "the presence of *B. coli* in milk necessarily indicates that it was contaminated with fecal matter." At Providence, streptococci in milk were considered an indication of "danger," of inflammation of the udder, etc.; at Washington, streptococci, in the opinion of the same witness, were of no significance, but were simply part of the flora of normal milk.

There is no need to continue the discouraging recital. Apart from the wreck of individual reputation which is sure to follow such rash tergiversation as here illustrated, there is another side to this question which, as a matter of general scientific policy, seems to us more important.

This is the responsibility that men of science should feel both to the community and to the professional body of which they form a part. This sense of responsibility should be rooted in a steadfastness of conviction which not only should make it impossible for these men to run with the hare and hunt with the hounds, but also should make them scrutinize the essential character of the cases and causes for which they are willing to appear in public. No one knows better than the skilled investigator how much uncertainty there still is concerning many matters on which definiteness would be of great practical importance. All the more reason why he should not utilize his expert knowledge of the factors of uncertainty to confuse public-health issues and throw dust in the eyes of the uninformed. To defend dishonest or careless milkmen by invoking the well-known technical difficulties in the way of interpreting bacterial analyses seems a questionable proceeding. There may be a difference of opinion as to the significance of a particular number or kind of bacteria in milk; there may be none as to the conviction of a particular milkman of carelessness or lack of cleanliness. On the occasion of a conspicuous ocean disaster a few years ago, it was said of a prominent steamship director that the situation in which he found himself demanded of him "a certain particularity of behavior." The situation of the modern man of science requires likewise a certain particularity of behavior. He owes his standing in the community in large part to the reputation for probity, candor and clear-headedness of the professional body to which he belongs. Every act of his tends to raise or lower in the public estimation the prestige and influence of the body of scholars with whom he is associated. He has obligations to his profession. Again, the non-technical public deserves from him an unwillingness to ally himself with doubtful causes, a clearness and steadiness of conviction and especially a disinclination to envelop scientific fact and interpretation in a cuttlefish murkiness of doubt and ambiguity.

---

[2] Ewins, A. J.: Acetylcholine, A New Active Principle of Ergot, Biochem. Jour., 1914, viii, 44.

We are aware that with regard to some questions public-health practice has outrun scientific judgment and needs to be set right. We know that the manifestation of personal pique and aggressiveness sometimes makes it necessary for scientific men to interpose in the interests of common fairness. Honest differences of opinion will sometimes cause men to align themselves on different sides of a *cause célèbre*. But it is clear also that there is far too much of the expert testimony which faces both ways, which befogs rather than illuminates, and which is partisan rather than candid. We appeal for a higher standard in this important field in which science has an opportunity to interpret itself to the community by making evident its disinterestedness and its desire most effectively to serve its time.

Current Comment

THE PROPHYLAXIS OF TETANUS

Statistics indicate[1] that probably there will be fewer deaths and injuries as a result of this year's celebration of the Fourth than of any previous year's. Notwithstanding, physicians cannot afford to overlook the possibility that they may have cases of tetanus to treat — and to prevent. In another column[2] we publish an article on the prophylaxis and therapy of tetanus. For convenience we here summarize the most important points in the prophylaxis:

1. Carefully and thoroughly remove every particle of foreign matter from the wound, laying it open, if necessary, under anesthesia.
2. Dry the wound thoroughly, and paint it and the surrounding parts as carefully as possible with iodin, or else cauterize it thoroughly with a 25 per cent. solution of phenol (carbolic acid) in glycerin or alcohol.
3. Apply a loose wet pack, using a solution of some such antiseptic substance as boric acid or alcohol.
4. As soon as possible inject intravenously or subcutaneously 1,500 units of antitetanic serum and continue the injections if indications of possible tetanus arise.
5. In no case close the wound. Allow it to heal by granulation. Remove the dressings and packing each day and apply fresh ones.

The loss of life from tetanus, it should be emphasized once more, is almost entirely preventable. Injection of antitoxin immediately after the injury is received, together with relentless surgical cleansing of the wound under anesthesia, constitutes insurance against tetanus in virtually every case. The few recorded cases in which antitoxin has failed to prevent tetanus have been attributable usually to a local infection which kept the tetanus bacillus alive until the antitoxin was eliminated or destroyed. Hence thorough cleansing of the injured part should not be neglected; and if the wound should suppurate, prophylactic injections of antitoxin should be repeated at intervals of eight or twelve days. If the patient is not seen until the wound is several days old, antitoxin should be given in large doses intravenously or, if symptoms indicate impending tetanus, intraspinally. The reasons for this course are given in a recent editorial.[3] In any case, promptness and thoroughness are the watchwords.

A CONTROVERTED THEORY OF NEPHRITIS

The theory of nephritis proposed by M. H. Fischer[1] has aroused considerable discussion and much criticism. One of the claims made by the Cincinnati physiologist in formulating his views on the subject is that any cell must, under conditions similar to those existing in the cells of the kidney when it is nephritic, be capable of serving as a source of albumin to a surrounding liquid medium, and so be capable of being responsible for a state which in the kidney goes by the name of albuminuria. According to this view, albuminuria represents merely that simple solution of the albumin of the kidney substance itself in the urine; that is, the protein does not come from the blood itself, except in that indirect way in which the proteins of any cell come originally from the blood. We have no desire to enter into a review of the controversy here further than to refer to the generally accepted belief that the urinary protein found in nephritis represents serum protein rather than tissue protein. Evidence in favor of this and contrary to Fischer's hypothesis has lately been offered by Dr. Salus[2] of the Hygienic Institute in the German University at Prague, Bohemia. Like previous investigators he has been able to develop a precipitin for human serum proteins by using albuminous urines as antigens. On the other hand, so-called organ plasma, a solution of tissue proteins prepared after completely removing the blood from various organs by Pohl's method, gave no reaction with the antiserum produced by injection of the protein excreted in nephritis. As, for the present, these biologic reactions offer the greatest promise of success in determining the identity of individual proteins, they place the burden of proof on those who maintain that the urinary protein of nephritis is merely the dissolved contribution of kidney cells subjected to an abnormal environment, rather than escaped blood components.

SPECIAL TRAINING FOR THE SPECIALIST

Notice is given elsewhere[1] of a two-year graduate course offered by the University of Minnesota to physicians desiring to specialize in diseases of the eye, ear, nose and throat. Satisfactory completion of this course will secure a suitable degree. This is a parallel to the graduate courses in public health given by five of our leading universities[2] preparatory to a special degree in public health. Such courses as these provided by high-grade universities will place the term "specialist" on a reliable basis. If such special courses are worth while for the development of public-health experts and for specialists in diseases of the eye, ear, nose and throat, why should not similar and equally thorough courses be established to furnish acceptable training in the other specialties of medicine? This idea may also hold a solution for the problems relating to special fields of practice now being exploited by various medical sects. Surely, before any one proposes to specialize in any particular field in the practice of medicine he should have secured, in addition to the usual medical course, further training in the diagnosis and treatment of the particular diseases included in that specialty. The establishment of the special graduate courses in public health by leading university medical schools and this special course for ophthalmologists at the University of Minnesota points to a new field in which there are great possibilities for the development of medical education.

BRITISH VIEWS OF AMERICAN MEDICAL ETHICS

Following the publication of the "Family Medical Encyclopedia" in England, as has been previously mentioned,[3] a storm of protest arose in the British Medical Association, at the publication of a list of contributors in such a book intended for the public. This type of medical advertising was severely condemned and likened to "the fever of self-advertisement which characterizes the American profession from tip to toe." In response to demands on the part of numerous members the Council of the British Medical Association has promulgated certain rules concerning the publication of medical books intended for the laity. These regulations are embodied in a letter from the London correspondent of The Journal, which appears on another page.[4] Without attempting, however, to discuss further the history of this monumental blunder — which may, perhaps, have been not entirely a blunder — on the part of so many well-known English medical men, let us revert to the point made in the previous editorial. It will be noted that our correspondent says: "It must be borne in mind that the professional rule against advertising is much more stringent in this country than in America." He voices, no doubt, the general impression of the foreign physician concerning American medical practitioners. When are these insults to cease? Can our foreign contemporaries point to a single incident in which medical men of America of equal rank with the English physicians concerned have loaned their names to such an outrageous enterprise? Can they point to a single American, connected with a reputable clinic, who would authorize and countenance the publication of such an obvious and misleading puff as was sanctioned by Drs. Krönig and Gauss in a recent issue of *McClure's?* Certainly, so far as we can determine, they will be unable to find one. The wise sanitarian will disinfect his own premises before naming as unclean the domicile of his neighbors.

THE DISTRIBUTION AND ELIMINATION OF ARSENIC IN THE BODY

Although arsenic can no longer claim the popularity that it once enjoyed as a "family poison," it is used often enough to make accurate information regarding its distribution in the organism desirable. Furthermore, the increasing use in practical medicine of the organic compounds of arsenic, notably salvarsan and its derivatives, emphasizes from the point of view of pharmacotherapy as well as that of the toxicologist and medicolegal expert, the need of knowledge respecting the fate of the drug in the body. We believe that we do not err in admitting that various investigators who have studied the retention of arsenic in the body have obtained results which decidedly disagree. A recent experiment in the department of physiology at the University of Missouri[1] has furnished data regarding the distribution of arsenic, in one case twenty-four hours after feeding 35 mg. to a fasting animal and before any elimination took place; in another, twenty days after administration of the same dose. The muscles retained the largest absolute amount of arsenic. In each case the metal was found to preponderate in the muscle, liver and intestine, respectively. In the animal killed early, the blood assumed fourth and the skin fifth place in the retention of the poison; but after twenty-one days these tissues had had time to lose all detectable arsenic. Their tendency is to eliminate it as rapidly as possible. It is interesting that the heart, although one of the smaller organs, is high in the order of retention, while the spleen, spinal cord, lung and kidney were lowest. No arsenic was excreted at any time with the feces. The results indicate, under the conditions presented in this research, that a single dose of arsenic, not large enough to disturb metabolism noticeably, is eliminated in about fifteen days.

STATISTICS OF FOURTH OF JULY INJURIES

The old life-destroying methods of celebrating Independence Day are tolerated less and less with each succeeding year. Public opinion has been aroused, the primary stimulus having been supplied by the annual statistics which we have collected and published for eleven years. Much of the credit for this work is due to the physicians who have kindly cooperated with us by sending in reports of cases. May we hope that this year also every physician who has a Fourth of July injury to attend will send us a report? What is desired is a brief mention of the actual injury, the immediate cause (the kind of cartridge or fireworks used) and the result. It is important that effort be not relaxed until the "safe and sane Fourth" has become permanently established everywhere.

Medical News

DISTRICT OF COLUMBIA

Hospital for Women.—The sundry civil bill report to the House of Representatives contained an item of $200,000 for the completion of a hospital for women.

Eradication of Tuberculosis.—The report of the District Health Department contains an elaborate account of its activities in limiting and ultimately suppressing tuberculosis. It is recommended that a campaign should be organized against this disease as a public health measure; that facilities for the treatment of incipient tuberculosis should be made available at hours adapted to the ordinary workingman; that the existing hospital facilities should be made available to the person in moderate circumstances; that some method should be provided whereby persons in moderate circumstances desiring to take treatment in their own homes could be assisted. The case-rate of tuberculosis in the district during the last fiscal year was 223 white persons and 643 colored persons per 100,000; and the death-rate from all forms of tuberculosis was 133 white and 504 colored; and that the rate for pulmonary tuberculosis alone per 100,000 was 120 white and 426 colored persons.

ILLINOIS

New Officers.—Galesburg Medical Society, June 2: president, Dr. Ralph C. Matheny; secretary-treasurer, Dr. Clarence B. Ripley.

Personal.—George Peter Dreyer, A.B., Ph.B., has been appointed dean of the junior faculty, professor of physiology and physiologic chemistry, and head of the department in the College of Physicians and Surgeons.——Dr. Charles F. W. Eberlein, chief of staff of the Oak Forest Infirmary, has resigned.

Sanatorium Notes.—The Kane County Anti-Tuberculosis League has planned a temporary tent colony, pending favorable action on the county tuberculosis sanatorium proposition. A site has been selected near Gilbert, and a donation of $2,000 has already been promised.——Plans for a new sanatorium building to be erected at Collinsville by the Harrison Tuberculosis Association have been completed, and ground is to be broken within the week. The building will be T-shaped, 176 feet deep, with a frontage of 35 feet and will accommodatae thirty patients.

Chicago

Chicago Medical Society Elects.—At the annual election, June 16, the following officers were elected: Dr. Charles J. Whalen, president; Dr. Charles E. Humiston, secretary.

Sanatorium Work Well Done.—Dr. Theodore B. Sachs, president of the board of trustees of the Municipal Tuberculosis Sanatorium, reports that the work on the sanatorium is being done according to contract, and that the institution will be ready for occupancy in November.

Meet after Fifty Years.—At the graduation exercises of the Northwestern University Medical School in Chicago, two graduates of the class of 1864 met for the first time since their graduation. They were Drs. Albert L. Converse of Springfield and P. J. Kelsey of New York City. A luncheon was given for the two alumni by President Harris of the University, at his home in Evanston.

Rush Alumni Elect.—At the annual meeting of the Alumni Association of Rush Medical College in Chicago, June 10, the following officers were elected: president, Dr. Arthur M. Corwin, Chicago; vice-presidents, Drs. Daniel H. Bowen, Waukon, Iowa; Charles J. Lewis, Chicago, and John R. McDill, Milwaukee; secretary, Dr. Charles A. Parker, Chicago; treasurer, Dr. Elmer E. Kenyon, Chicago, and necrologist, Dr. John J. Stoll, Chicago.

Internship Required.—The faculty of the Northwestern University Medical College, at a recent meeting, voted that hereafter every student who matriculates will be required to spend at least one year as an intern, and in an acceptable hospital, before a degree will be given. This school is the fourth medical school to make hospital internship a condition for a degree, the other schools being University of Minnesota Medical Department, Rush Medical College and the Medical Department of Leland Stanford University.

Bust of Dr. Steele Presented.—On June 10 a bust of Dr. D. A. K. Steele was presented to the College of Physicians and Surgeons of the University of Illinois by the faculty and alumni of the college. The presentation was made by Dr. Adolph Gehrmann and the bust was accepted by President James of the university. It was largely through Dr. Steele's efforts that the organization of the College of Physicians and Surgeons was united with the University of Illinois, and for more than thirty years Dr. Steele has devoted his efforts to the supporting and upbuilding of the school.

Alumni Meeting.—At the alumni meeting of the Association of the College of Physicians and Surgeons of the University of Illinois, held in Chicago, June 10, addresses were made by President Edmund Janes James of the university, who announced a plan of asking $1,000,000 from the legislature for the construction and endowment of a teaching hospital as a part of the university; by W. S. Abbott, president of the board of trustees, and Dr. Albert L. Brittin, Leslie, Ill., president of the Illinois State Medical Society. The following officers were elected: president, Dr. J. M. Berger; vice-presidents, Drs. Charles H. Phifer and George J. Lorch; secretary, Dr. Frank Chauvet; treasurer, Dr. Robert N. Morris, all of Chicago.

INDIANA

Hospital Units Ready.—The State Board of Health expects to occupy two units of the State Hospital next week, and has asked the city comptroller to recommend a temporary loan to the city council of $65,000 for the use of the board.

A Clinic for Babies.—A clinic for examining babies and to give advice to mothers concerning the child's health and diet is being maintained by the Children's Association of Indianapolis. The stations are in charge of Drs. J. Don Miller, Walter D. Hoskins, Leslie H. Maxwell and Lehman M. Dunning.

Disease Prevention Day.—The governor has consented to issue a proclamation calling the people of the state to observe a day in October, to be designated as Disease Prevention Day. Sixty antituberculosis societies will lead in observing the day, and will have the cooperation of the State Board of Health, the State Anti-Tuberculosis Society and municipal officers of many cities.

Personal.—Dr. T. Victor Keene has been elected president and Dr. Thomas B. Eastman vice-president of the Board of Health of Indianapolis.——Dr. J. Willard Parrish, Shelbyville, has been appointed physician of the Shelby County Orphans' Home.——Dr. Gustavus B. Jackson has been appointed a member of the Indianapolis Board of Health, vice Dr. Mavity J. Spencer, term expired.——Dr. Henry O. Wells, Fort Wayne, has been elected president of the Blue Cass Springs Sanatorium, Woodburn.

Long Hospital Dedicated.—Dedicatory exercises of the Robert W. Long Hospital were held in the chambers of the House of Representatives, June 15. Governor Ralston presided and an address was delievered by Dr. Henry J. Pritchett, president of the Carnegie Institute for Medical

Teaching, on "Medical Schools and the State." The guests were taken to the Robert W. Long hospital where the dedicatory exercises proper were held, in the East room. Dr. and Mrs. Robert W. Long formally presented the hospital to the state and Governor Ralston accepted the gift in behalf of the state. In the evening a banquet was given at the Claypool Hotel, where Dr. Pritchett, President Bryan of the Indiana University, Governor Ralston, Mayor Bell of Indianapolis and others delivered addresses.

Verdict in Favor of Physicians.—The suit brought by Mrs. Anna Harrell of Shelby County against Drs. Orange G. Pfaff of Indianapolis and Moris Drake of Shelbyville for alleged malpractice resulted in a verdict in favor of the physicians in the Shelby County court, June 9. The plaintiff asked $20,000 damages on account of the failure of the surgeons to remove a piece of gauze from plaintiff's abdomen following an operation for ruptured ectopic pregnancy, as alleged, the gauze coming away later, after having caused the patient great suffering. The surgeons showed that the gauze had been placed in the culdesac of Douglass for drainage purposes, and in a careful professional manner.

IOWA

Iowa Medical Journal Suspends Publication.—The *Iowa Medical Journal* has discontinued publication and has been succeeded by *The Journal of the Iowa State Medical Society.*

Personal.—Dr. Amos W. Carlile has been appointed local surgeon of the Chicago and Northwestern System at Manning, vice Dr. Robert R. Williams, resigned.——Dr. Curtis E. Bower, Arlington, has given up his practice on account of ill health, and will make his home in Colorado.——Dr. Charles H. Bower has been appointed health physician of Council Bluffs.——Dr. Mary Lawson Neff has returned to her home in Des Moines after six weeks spent in the state reformatory, doing special psychologic work.——Dr. W. Eugene Walcott, Merrill, and Dr. and Mrs. Donald Macrea, Jr., Council Bluffs, have sailed for Europe.——Drs. Fred J. McAllister and Albert J. Meyer have purchased a house in Hawarden which they will remodel and convert into a hospital.——Dr. Arthur H. McCreight and family, Fort Dodge, have returned from Europe

MARYLAND

Alumni Reunion.—The alumni of the College of Physicians and Surgeons, Baltimore, will make their headquarters at the Alamac Hotel, Atlantic City, during the meeting of the American Medical Association.

Personal.—Dr. William D. Cawley, Elkton, has been appointed physician at the Cecil County Insane Asylum, vice Dr. Philip B. Housekeeper, North East, deceased.——Dr. Philip Briscoe, Mutual, Calvert County, has been elected president of the State Board of Aid and Charity.

Graduate Nurses for the Insane.—Six women and two men received certificates of graduation from the Nurses' Training School of Springfield State Hospital for the Insane on June 9, the first class of this kind to be formed in a Maryland institution for mental cases. Dr. Adolf Meyer, director of the Henry Phipps Psychiatric Clinic of Johns Hopkins Hospital, made the address to the graduates and the certificates were conferred by Dr. Arthur P. Herring, secretary of the State Lunacy Commission.

Important Post for Professor Whipple.—Dr. George Hoyt Whipple, associate professor of Johns Hopkins University, has been chosen director of the Hooper Foundation for Medical Research by the board of regents of the University of California. Dr. Whipple is widely known in his profession. He is a graduate of Yale University and the Johns Hopkins Medical School. He served for several years in the Ancon Hospital in the Panama Canal Zone and is a member of many medical and research societies.

Medico-Psychological Meeting.—The seventieth annual meeting of the American Medico-Psychological Association, held in Baltimore from May 26 to 29, proved most successful. Addresses of welcome were delivered by Gov. Phillips Lee Goldsborough, Mayor James H. Preston, Dr. Hugh H. Young and Dr. Randolph Winslow. The response was made by Dr. Carlos F. MacDonald, New York City, president of the association. The officers elected are: Dr. Samuel E. Smith, Richmond, Ind., president; Dr. Edward N. Brush, Towson, Md., vice-president; Dr. Charles D. Wagner, Binghamton, N. Y., secretary. The place chosen for the next session was Old Point Comfort, Va.

MISSOURI

Physician's Portrait Presented.—A life-size oil portrait of Dr. Joseph M. Wood, a pioneer practitioner of Kansas City, was presented by his daughter to the Board of Education of Kansas City, May 21. Historical reminiscences of Dr. Wood were given by Drs. Edward W. Schauffler and David R. Porter.

Personal.—Dr. Rush E. Castelaw has resigned as head of the Kansas City Hospital.——Dr. George R. Thompson, St. Joseph, was elected superintendent of State Hospital No. 2 on June 4, vice Dr. Abra C. Pettijohn. The officers and employees of the institution presented Dr. Pettijohn with a diamond stick-pin.——Dr. Frank W. Flower, Carthage, announces that after forty years of active practice he will retire from the practice of medicine.——Dr. William T. Elam, St. Joseph, charged with killing W. K. Cramer, Chicago, was acquitted by the jury, May 29.—Dr. Oliver W. H. Mitchell, Columbia, has assumed his duties as city bacteriologist of Syracuse, N. Y.——Drs. Louis J. Danadurant, Floyd H. Spencer, Joseph J. Bansbach and Clarence A. Good, St. Joseph, returned from Europe, May 26.——Dr. John C. Kessenger, Milan, was operated on in Rochester, Minn., May 13, and is reported to be doing well.

St. Louis

Dispensary Moves.—The evening dispensary for women, which has been located at 1607 Washington Street for twenty-one years, has moved and its quarters are now at 510 North Fifteenth Street. Clinics are held on Monday, Thursday and Friday from 7 to 9 p. m.

Personal.—Dr. Carl Orth has returned from Europe.——Dr. Charles H. Eyermann has succeeded Dr. Theodore P. Brookes as assistant physician of the city dispensary. Dr. Brookes has started for Europe.——Dr. and Mrs. Lucius A. Walton celebrated their fiftieth wedding anniversary, May 26.

NEW YORK

Long Island Doctors Meet.—The fortieth annual meeting of the Associated Physicians of Long Island was held at Avery's Five Mile Look on June 6. Dr. Walter A. Sherwood presided. Among those who made addresses were Drs. James V. May, Port Gibson, Miss., and A. J. Rosenoff. The scientific session was followed by a shore dinner.

Buffalo Alumni Elect.—At the fortieth annual meeting of the University of Buffalo Alumni Association, June 3: president, Dr. George F. Cott, Buffalo; vice-presidents, Drs. Robert T. French, Rochester, N. Y.; William B. Hare, Portland, Ore.; Abram T. Kerr, Ithaca; Burt C. Johnson, Buffalo, and Mary B. Moody, Los Angeles; secretary, Dr. Julius Richter, Buffalo; treasurer, Dr. William F. Jacobs, Buffalo.

May Stop Hospital Inquiry.—It is intimated that the state authorities have not been pleased at the manner in which the State Hospital has been conducting its investigation, especially with regard to the quality of the food supplies. It is held that the hospital commission is itself under fire and that it has shown a tendency to exonerate the attaches of the various hospitals and has gone out of its way to discredit the testimony of the federal inspectors.

New York City

Gift to New York Academy of Medicine.—Dr. Rowland G. Freeman has presented the library of the New York Academy of Medicine a fine copy of Bidloo (Godefridus) Anatomia humani corporis, 105 plates, folio. Amstelodami, vid. J. a Someren, 1685.

Hospital Needs Money.—A campaign has been started to raise $150,000 for St. John's Hospital, Long Island City. The money is needed to enlarge the hospital as it is the most important institution of its kind in Queens and is overcrowded most of the time.

Removal of Brooklyn Clinic.—The Brooklyn Antirabic Clinic, until recently conducted at the Brooklyn Borough Office, will be removed to 29 Third Avenue. It will be open on week days from 10 a. m. to 1 p. m., and on Sundays and holidays, for all cases from the boroughs.

Typhus Fever Patient Comes to Port.—The *President Grant* arrived at Quarantine recently with a case of typhus fever in a child 9 years of age, on board. The 226 steerage passengers who occupied the same section were transferred to Swinburne Island to undergo two weeks' observation.

Doctors' and Nurses' Home.—The Architectural Bureau of the Department of Health has filed plans for the construction of a seven-story building with basement for the doctors and nurses of the Willard Parker Hospital. The building will be fire-proof, reinforced concrete construction, with a frontage of 100 feet, and a depth of 82½ feet, and will cost $250,000.

Milk Depots Open.—Ten additional milk stations were opened on June 2 by Mr. Nathan Straus. This makes eighteen which he supports during the summer and eight during the entire year. At all of these stations milk suitably modified and pasteurized for infant feeding is furnished at less than the cost price. Mr. Straus has carried on this charity since 1892.

Milk-Supply.—The report of the Department of Health on the city milk-supply shows that at the present time about 99 per cent. of the total supply is being satisfactorily pasteurized, and that the pasteurizing plants are subject to close supervision by the department. Large numbers of samples of milk are examined bacteriologically to check up efficiency of operation.

To Investigate Coroner's Office.—The City Club has asked Mayor Mitchell to make an investigation of the coroner's office and the mayor has directed the commissioner of accounts to begin the investigation at once. Aside from dereliction of duty it is believed that the charter organization of the office does not make for efficient administration and it is hoped that this investigation will be of constructive value.

Medical Schools Graduate.—The annual commencement exercises of the College of Physicians and Surgeons of Columbia University and of the New York University and Bellevue Hospital Medical College were held on June 10. The graduating class numbered seventy-one men. The Hippocratic oath was administered by the dean of the college, Dr. Samuel W. Lambert. All the graduates of the University and Bellevue Hospital Medical School received hospital appointments. On this occasion the honorary degree of doctor of science was conferred on Dr. Aristides Agramonte of Havana.

Bichlorid Poisoning.—The ordinance restricting the retail sale of bichlorid of mercury tablets in Greater New York went into effect on March 1. The records which have been collected from the coroner's office show that there were ten deaths from bichlorid poisoning during the period from March 1 to June 1; six of these were suicides and four were accidental. This is a considerable decrease in the number of deaths from poisoning by this drug and it is believed the decrease will be much more marked hereafter as supplies which were kept in homes will become exhausted and cannot be replaced.

Personal.—Dr. Lester D. Volk and Dr. Gerard Kasper have resigned their positions as coroner's physicians in Brooklyn.——Dr. Arthur H. Elliott of Brooklyn and Dr. and Mrs. William S. Dennett of Manhattan have sailed for Europe.——Dr. and Mrs. J. Leeming Walker of London, Eng., arrived in this country on Tuesday; they will occupy the cottage of Dr. H. Holbrook Curtis for the season.——Dr. Anna Hubert of Seattle, Wash., has been appointed resident physician at the workhouse on Blackwell's Island. This appointment provides for the examination of female prisoners by a woman.—Drs. Annie S. Daniels and W. I. Hull have sailed for Europe.

NORTH CAROLINA

Fresh-Air Camp for Babies.—The establishment of a fresh-air camp and sanitarium for babies at Saluda was enthusiastically endorsed at a meeting held in Spartanburg, S. C., May 29, and a committee was appointed to promote the plan.

Do Not Wish Appropriation Reduced.—Five hundred representative citizens of Wilmington at a mass-meeting, June 2, adopted resolutions demanding that the city council reconsider its action of reducing the annual appropriation for the city health department below the amount agreed on by the municipal health officers and the county commissioner.

Personal.—Dr. Richard H. Lewis, Raleigh, who has served for more than thirty years as trustee of the university, and for the major portion of that time as secretary of the board, has resigned on account of ill health.——Dr. Walter C. Ashworth, Greensboro, president and director of the Glenwood Park, Telfair, Sanitarium, has gone to Europe. Dr. Howard S. Kinne, Loganton, Pa., will have charge of the sanitarium in Dr. Ashworth's absence.

OHIO

Personal.—Dr. A. W. Davis, city health officer of Canal Dover, has resigned.——Dr. Valloyd Adair, as the result of competitive examinations, has been appointed health officer of Lorain.——Dr. Morris C. Tuholske has been reappointed medical examiner of the public schools of Akron.——Dr. Rockwell B. Hubbard, Sandusky, was seriously injured, recently, as a result of a head-on collision between his automobile and an electric train.

Hospital Notes.—At a meeting of the citizens of Barberton, June 2, it was decided immediately to incorporate a stock company for the purpose of erecting a hospital, to cost from $50,000 to $60,000, and to be known as the City Hospital Company of Barberton. Dr. William A. Mansfield was elected temporary president, and Dr. Herbert A. Rodenbaugh, temporary secretary of the organization.——The cornerstone of St. Elizabeth's Hospital, Youngstown, was laid by Bishop Farrelly, May 30. The building is expected to be ready for occupancy early in January of next year. ——A new hospital is to be built in Fremont, to cost $150,000. Of this sum, $100,000 was bequeathed to the city on the condition that an additional sum of $50,000 be raised by the citizens.

Trachoma in Ohio.—Dr. F. G. Baudreau of the State Board of Health, found 23 of the 80 inmates of the Athens County Children's Home suffering from trachoma. Since the report by Dr. Joseph W. Schereschewsky, Washington, of the Public Health Service concerning trachoma in the employees of the Youngstown Sheet and Tube Works at East Youngstown, and on the generally bad sanitary conditions of the town, overcrowding of lodging and boarding houses, etc., action has been taken to remedy conditions by the town council. The medical department of the Sheet and Tube Works has also instituted many reforms, have bettered sanitary conditions, and are cooperating with the city authorities. The trachoma hospital established by the company will soon be supplied with tub and shower baths for the benefit of the citizens generally and the employees of the company, for the use of which a very small fee will be charged. The council was recently addressed by Dr. Sidney M. McCurdy, chief surgeon, and J. M. Wolz, head of the safety department of the Sheet and Tube Works, on the necessity for better housing and better municipal sanitation.

Cincinnati

Honor to Kramer.—Dr. Simon P. Kramer was given a banquet by physicians of Cincinnati, May 20, at which Dr. Charles L. Bonifield was toastmaster.

Contagious Disease Hospital.—Plans have been completed for the contagious portion of the General Hospital, which is to be constructed west of the tuberculosis group at Lick Run. The building will be two stories and basement in height, 140 feet in depth and will cost $35,000.

Academy Clinics.—A series of interesting clinics were held under the auspices of the Cincinnati Academy of Medicine at the City Hospital, by Drs. William D. Haggard, Nashville, Tenn.; Dr. Wendell C. Phillips, New York City, and Richard C. Cabot, Boston, on the mornings of June 10, 11 and 12.

Summer Lectures.—On June 9, the Health Department inaugurated a series of lectures for district physicians, school nurses, supervisors of nurses and visiting nurses. One June 9, Dr. Frank H. Lamb spoke on "Physiology in Metabolism"; on June 10, Dr. Alfred Friedlander spoke on "The Treatment of Gastro-Enteritis and Other Diseases Peculiar to Children," and on June 11, Dr. Benjamin K. Rachford spoke on "Infant-Feeding."

PENNSYLVANIA

Philadelphia

American Orthopedic Association.—Clinical Day of the twenty-ninth annual meeting of the American Orthopedic Association was held at the University Hospital on Wednesday, June 17.

Rapid Transit Safety Contest.—The Safety Bureau of the Rapid Transit Company has awarded prizes for essay, verse or drawing expressing a practical means of prevention of street accidents. The contest was opened to children in the city schools.

To Stimulate War on Flies.—Director Harte of the Department of Public Health and Charities has started a fly-catching

Teaching, on "Medical Schools and the State." The guests were taken to the Robert W. Long hospital where the dedicatory exercises proper were held, in the East room. Dr. and Mrs. Robert W. Long formally presented the hospital to the state and Governor Ralston accepted the gift in behalf of the state. In the evening a banquet was given at the Claypool Hotel, where Dr. Pritchett, President Bryan of the Indiana University, Governor Ralston, Mayor Bell of Indianapolis and others delivered addresses.

Verdict in Favor of Physicians.—The suit brought by Mrs. Anna Harrell of Shelby County against Drs. Orange G. Pfaff of Indianapolis and Moris Drake of Shelbyville for alleged malpractice resulted in a verdict in favor of the physicians in the Shelby County court, June 9. The plaintiff asked $20,000 damages on account of the failure of the surgeons to remove a piece of gauze from plaintiff's abdomen following an operation for ruptured ectopic pregnancy, as alleged, the gauze coming away later, after having caused the patient great suffering. The surgeons showed that the gauze had been placed in the culdesac of Douglass for drainage purposes, and in a careful professional manner.

IOWA

Iowa Medical Journal Suspends Publication.—The *Iowa Medical Journal* has discontinued publication and has been succceeded by *The Journal of the Iowa State Medical Society.*

Personal.—Dr. Amos W. Carlile has been appointed local surgeon of the Chicago and Northwestern System at Manning, vice Dr. Robert R. Williams, resigned.——Dr. Curtis E. Bower, Arlington, has given up his practice on account of ill health, and will make his home in Colorado.——Dr. Charles H. Bower has been appointed health physician of Council Bluffs.——Dr. Mary Lawson Neff has returned to her home in Des Moines after six weeks spent in the state reformatory, doing special psychologic work.——Dr. W. Eugene Walcott, Merrill, and Dr. and Mrs. Donald Macrea, Jr., Council Bluffs, have sailed for Europe.——Drs. Fred J. McAllister and Albert J. Meyer have purchased a house in Hawarden which they will remodel and convert into a hospital.——Dr. Arthur H. McCreight and family, Fort Dodge, have returned from Europe.

MARYLAND

Alumni Reunion.—The alumni of the College of Physicians and Surgeons, Baltimore, will make their headquarters at the Alamac Hotel, Atlantic City, during the meeting of the American Medical Association.

Personal.—Dr. William D. Cawley, Elkton, has been appointed physician at the Cecil County Insane Asylum, vice Dr. Philip B. Housekeeper, North East, deceased.——Dr. Philip Briscoe, Mutual, Calvert County, has been elected president of the State Board of Aid and Charity.

Graduate Nurses for the Insane.—Six women and two men received certificates of graduation from the Nurses' Training School of Springfield State Hospital for the Insane on June 9, the first class of this kind to be formed in a Maryland institution for mental cases. Dr. Adolf Meyer, director of the Henry Phipps Psychiatric Clinic of Johns Hopkins Hospital, made the address to the graduates and the certificates were conferred by Dr. Arthur P. Herring, secretary of the State Lunacy Commission.

Important Post for Professor Whipple.—Dr. George Hoyt Whipple, associate professor of Johns Hopkins University, has been chosen director of the Hooper Foundation for Medical Research by the board of regents of the University of California. Dr. Whipple is widely known in his profession. He is a graduate of Yale University and the Johns Hopkins Medical School. He served for several years in the Ancon Hospital in the Panama Canal Zone and is a member of many medical and research societies.

Medico-Psychological Meeting.—The seventieth annual meeting of the American Medico-Psychological Association, held in Baltimore from May 26 to 29, proved most successful. Addresses of welcome were delivered by Gov. Phillips Lee Goldsborough, Mayor James H. Preston, Dr. Hugh H. Young and Dr. Randolph Winslow. The response was made by Dr. Carlos F. MacDonald, New York City, president of the association. The officers elected are: Dr. Samuel E. Smith, Richmond, Ind., president; Dr. Edward N. Brush, Towson, Md., vice-president; Dr. Charles D. Wagner, Binghamton, N. Y., secretary. The place chosen for the next session was Old Point Comfort, Va.

MISSOURI

Physician's Portrait Presented.—A life-size oil portrait of Dr. Joseph M. Wood, a pioneer practitioner of Kansas City, was presented by his daughter to the Board of Education of Kansas City, May 21. Historical reminiscences of Dr. Wood were given by Drs. Edward W. Schauffler and David R. Porter.

Personal.—Dr. Rush E. Castelaw has resigned as head of the Kansas City Hospital.——Dr. George R. Thompson, St. Joseph, was elected superintendent of State Hospital No. 2 on June 4, vice Dr. Abra C. Pettijohn. The officers and employees of the institution presented Dr. Pettijohn with a diamond stick-pin.——Dr. Frank W. Flower, Carthage, announces that after forty years of active practice he will retire from the practice of medicine.——Dr. William T. Elam, St. Joseph, charged with killing W. K. Cramer, Chicago, was acquitted by the jury, May 29.—Dr. Oliver W. H. Mitchell, Columbia, has assumed his duties as city bacteriologist of Syracuse, N. Y.——Drs. Louis J. Danadurant, Floyd H. Spencer, Joseph J. Bansbach and Clarence A. Good, St. Joseph, returned from Europe, May 26.——Dr. John C. Kessenger, Milan, was operated on in Rochester, Minn., May 13, and is reported to be doing well.

St. Louis

Dispensary Moves.—The evening dispensary for women, which has been located at 1607 Washington Street for twenty-one years, has moved and its quarters are now at 510 North Fifteenth Street. Clinics are held on Monday, Thursday and Friday from 7 to 9 p. m.

Personal.—Dr. Carl Orth has returned from Europe.——Dr. Charles H. Eyermann has succeeded Dr. Theodore P. Brookes as assistant physician of the city dispensary. Dr. Brookes has started for Europe.——Dr. and Mrs. Lucius A. Walton celebrated their fiftieth wedding anniversary, May 26.

NEW YORK

Long Island Doctors Meet.—The fortieth annual meeting of the Associated Physicians of Long Island was held at Avery's Five Mile Look on June 6. Dr. Walter A. Sherwood presided. Among those who made addresses were Drs. James V. May, Port Gibson, Miss., and A. J. Rosenoff. The scientific session was followed by a shore dinner.

Buffalo Alumni Elect.—At the fortieth annual meeting of the University of Buffalo Alumni Association, June 3: president, Dr. George F. Cott, Buffalo; vice-presidents, Drs. Robert T. French, Rochester, N. Y.; William B. Hare, Portland, Ore.; Abram T. Kerr, Ithaca; Burt C. Johnson, Buffalo, and Mary B. Moody, Los Angeles; secretary, Dr. Julius Richter, Buffalo; treasurer, Dr. William F. Jacobs, Buffalo.

May Stop Hospital Inquiry.—It is intimated that the state authorities have not been pleased at the manner in which the State Hospital has been conducting its investigation, especially with regard to the quality of the food supplies. It is held that the hospital commission is itself under fire and that it has shown a tendency to exonerate the attaches of the various hospitals and has gone out of its way to discredit the testimony of the federal inspectors.

New York City

Gift to New York Academy of Medicine.—Dr. Rowland G. Freeman has presented the library of the New York Academy of Medicine a fine copy of Bidloo (Godefridus) Anatomia humani corporis, 105 plates, folio. Amstelodami, vid. J. a Someren, 1685.

Hospital Needs Money.—A campaign has been started to raise $150,000 for St. John's Hospital, Long Island City. The money is needed to enlarge the hospital as it is the most important institution of its kind in Queens and is overcrowded most of the time.

Removal of Brooklyn Clinic.—The Brooklyn Antirabic Clinic, until recently conducted at the Brooklyn Borough Office, will be removed to 29 Third Avenue. It will be open on week days from 10 a. m. to 1 p. m., and on Sundays and holidays, for all cases from the boroughs.

Typhus Fever Patient Comes to Port.—The *President Grant* arrived at Quarantine recently with a case of typhus fever in a child 9 years of age, on board. The 226 steerage passengers who occupied the same section were transferred to Swinburne Island to undergo two weeks' observation.

Doctors' and Nurses' Home.—The Architectural Bureau of the Department of Health has filed plans for the construction of a seven-story building with basement for the doctors and nurses of the Willard Parker Hospital. The building will be fire-proof, reinforced concrete construction, with a frontage of 100 feet, and a depth of 82½ feet, and will cost $250,000.

Milk Depots Open.—Ten additional milk stations were opened on June 2 by Mr. Nathan Straus. This makes eighteen which he supports during the summer and eight during the entire year. At all of these stations milk suitably modified and pasteurized for infant feeding is furnished at less than the cost price. Mr. Straus has carried on this charity since 1892.

Milk-Supply.—The report of the Department of Health on the city milk-supply shows that at the present time about 99 per cent. of the total supply is being satisfactorily pasteurized, and that the pasteurizing plants are subject to close supervision by the department. The graduating class numbered seventy-one men. The Hippocratic oath was administered by the dean of the college, Dr. Samuel W. Lambert. All the graduates of the University and Bellevue Hospital Medical School received hospital appointments. On this occasion the honorary degree of doctor of science was conferred on Dr. Aristides Agramonte of Havana.

Bichlorid Poisoning.—The ordinance restricting the retail sale of bichlorid of mercury tablets in Greater New York went into effect on March 1. The records which have been collected from the coroner's office show that there were ten deaths from bichlorid poisoning during the period from March 1 to June 1; six of these were suicides and four were accidental. This is a considerable decrease in the number of deaths from poisoning by this drug and it is believed the decrease will be much more marked hereafter as supplies which were kept in homes will become exhausted and cannot be replaced.

Personal.—Dr. Lester D. Volk and Dr. Gerard Kasper have resigned their positions as coroner's physicians in Brooklyn.——Dr. Arthur H. Elliott of Brooklyn and Dr. and Mrs. William S. Dennett of Manhattan have sailed for Europe.——Dr. and Mrs. J. Leeming Walker of London, Eng., arrived in this country on Tuesday; they will occupy the cottage of Dr. H. Holbrook Curtis for the season.——Dr. Anna Hubert of Seattle, Wash., has been appointed resident physician at the workhouse on Blackwell's Island. This appointment provides for the examination of female prisoners by a woman.—Drs. Annie S. Daniels and W. I. Hull have sailed for Europe.

NORTH CAROLINA

Fresh-Air Camp for Babies.—The establishment of a fresh-air camp and sanitarium for babies at Saluda was enthusiastically endorsed at a meeting held in Spartanburg, S. C., May 29, and a committee was appointed to promote the plan.

Do Not Wish Appropriation Reduced.—Five hundred representative citizens of Wilmington at a mass-meeting, June 2, adopted resolutions demanding that the city council reconsider its action of reducing the annual appropriation for the city health department below the amount agreed on by the municipal health officers and the county commissioner.

Personal.—Dr. Richard H. Lewis, Raleigh, who has served for more than thirty years as trustee of the university, and for the major portion of that time as secretary of the board, has resigned on account of ill health.——Dr. Walter C. Ashworth, Greensboro, president and director of the Glenwood Park, Telfair, Sanitarium, has gone to Europe. Dr. Howard S. Kinne, Loganton, Pa., will have charge of the sanitarium in Dr. Ashworth's absence.

OHIO

Personal.—Dr. A. W. Davis, city health officer of Canal Dover, has resigned.——Dr. Valloyd Adair, as the result of competitive examinations, has been appointed health officer of Lorain.——Dr. Morris C. Tuholske has been reappointed medical examiner of the public schools of Akron.——Dr. Rockwell B. Hubbard, Sandusky, was seriously injured, recently, as a result of a head-on collision between his automobile and an electric train.

Hospital Notes.—At a meeting of the citizens of Barberton, June 2, it was decided immediately to incorporate a stock company for the purpose of erecting a hospital, to cost from $50,000 to $60,000, and to be known as the City Hospital Company of Barberton. Dr. William A. Mansfield was elected temporary president, and Dr. Herbert A. Rodenbaugh, temporary secretary of the organization.——The cornerstone of St. Elizabeth's Hospital, Youngstown, was laid by Bishop Farrelly, May 30. The building is expected to be ready for occupancy early in January of next year.——A new hospital is to be built in Fremont, to cost $150,000. Of this sum, $100,000 was bequeathed to the city on the condition that an additional sum of $50,000 be raised by the citizens.

Trachoma in Ohio.—Dr. F. G. Baudreau of the State Board of Health, found 23 of the 80 inmates of the Athens County Children's Home suffering from trachoma. Since the report by Dr. Joseph W. Schereschewsky, Washington, of the Public Health Service concerning trachoma in the employees of the Youngstown Sheet and Tube Works at East Youngstown, and on the generally bad sanitary conditions of the town, overcrowding of lodging and boarding houses, etc., action has been taken to remedy conditions by the town council. The medical department of the Sheet and Tube Works has also instituted many reforms, have bettered sanitary conditions, and are cooperating with the city authorities. The trachoma hospital established by the company will soon be supplied with tub and shower baths for the benefit of the citizens generally and the employees of the company, for the use of which a very small fee will be charged. The council was recently addressed by Dr. Sidney M. McCurdy, chief surgeon, and J. M. Wolz, head of the safety department of the Sheet and Tube Works, on the necessity for better housing and better municipal sanitation.

Cincinnati

Honor to Kramer.—Dr. Simon P. Kramer was given a banquet by physicians of Cincinnati, May 20, at which Dr. Charles L. Bonifield was toastmaster.

Contagious Disease Hospital.—Plans have been completed for the contagious portion of the General Hospital, which is to be constructed west of the tuberculosis group at Lick Run. The building will be two stories and basement in height, 140 feet in depth and will cost $35,000.

Academy Clinics.—A series of interesting clinics were held under the auspices of the Cincinnati Academy of Medicine at the City Hospital, by Drs. William D. Haggard, Nashville, Tenn.; Dr. Wendell C. Phillips, New York City, and Richard C. Cabot, Boston, on the mornings of June 10, 11 and 12.

Summer Lectures.—On June 9, the Health Department inaugurated a series of lectures for district physicians, school nurses, supervisors of nurses and visiting nurses. One June 9, Dr. Frank H. Lamb spoke on "Physiology in Metabolism"; on June 10, Dr. Alfred Friedlander spoke on "The Treatment of Gastro-Enteritis and Other Diseases Peculiar to Children," and on June 11, Dr. Benjamin K. Rachford spoke on "Infant-Feeding."

PENNSYLVANIA

Philadelphia

American Orthopedic Association.—Clinical Day of the twenty-ninth annual meeting of the American Orthopedic Association was held at the University Hospital on Wednesday, June 17.

Rapid Transit Safety Contest.—The Safety Bureau of the Rapid Transit Company has awarded prizes for essay, verse or drawing expressing a practical means of prevention of street accidents. The contest was opened to children in the city schools.

To Stimulate War on Flies.—Director Harte of the Department of Public Health and Charities has started a fly-catching contest, opened to every boy scout. Prizes have been offered to those who catch the largest number. The contest will be conducted by the various troops, and the troop-master will be judge of the boys within his troop.

Small Appropriation for Mosquito Extermination.—Councils have appropriated only $1,400 to fight mosquitoes in this city. A meager fund with which to break up the breeding-places in the marshes and pools around Philadelphia, which is always open to breeding-places for mosquitoes, as 8,500 acres of the city's area is below the level of high water of Delaware and Schuylkill Rivers.

Women to Enter Medical Department of the University of Pennsylvania.—It has been announced that the Medical Department of the University of Pennsylvania has decided to open the doors of its medical department to women. It has been stated that this announcement will be made officially at the annual commencement. It is also predicted that the dental department will be opened later to women.

Personal.—Dr. James Tyson was a guest of Chief Surgeon George W. Reese of the Shamokin Hospital on May 27, and guest of honor of the Shamokin Medical Society at a banquet at the Windsor Hotel the same evening. Dr. A. MacKensie Forbes of Montreal, Canada, will give a demonstration of his method of applying a plaster cast in treatment or correction of scoliosis, at the Methodist Hospital, on Monday June 22, at 10:30 o'clock.

Campaign for West Philadelphia Hospital.—The campaign to raise $150,000 for the new building for the West Philadelphia General Homeopathic Hospital opened with a dinner to the captains at the campaign headquarters, in Horticultural Hall, June 9. A large clock has been built at Fifty-Second and Chestnut Streets to indicate the returns, and forty-five smaller clocks have been placed in prominent places in West Philadelphia. At the end of the third day a total of $23,917 had been subscribed.

Hospital News.—The Municipal Summer Hospitals for the care of sick children and infants were opened at the Race Street and Chestnut Street piers, June 15. Councils placed $6,500 at the disposal of the director of health to increase the accommodations of both these hospitals. Dr. S. W. Newmayer, assistant medical inspector, has charge of the Chestnut Street pier, which is equipped with twenty beds and a corps of three nurses.——The new Jewish Maternity Hospital at Sixth and Spruce Streets was dedicated June 9.——The contract for two additions to the St. Mary's Hospital has just been awarded. The new structure, of brick with stone and terra-cotta trimmings, will consist of a five-story and basement wing to be built on Palmer Street, a distance of about 170 feet, with another wing along Sepviva Street, a distance of 68 feet. The greater portion of this wing will be five stories high and will contain a convent for sisters and a power-house with a laundry. There will be a roof garden with facilities for the treatment of sunstroke and heat cases. The main entrance will be on Palmer Street.

TENNESSEE

Colleges Merged.—It is reported that the Lincoln Memorial University Medical Department of Knoxville has merged with the University of Tennessee College of Medicine, located at Memphis. Under the terms of the merger, the three remaining classes will be taught at the University of Tennessee, but the degrees will be granted by the Lincoln Memorial University. The last class will be graduated, therefore, in 1917.

TEXAS

Sanatorium Burns.—The tuberculosis sanatorium at 219 Dullnig Street, San Antonio, was destroyed by fire, May 29, with a loss of about $3,000.

New Officers.—North East Texas Medical Association at Texarkana, June 2: president, Dr. Robert H. T. Mann; secretary, Dr. Edwin L. Beck, both of Texarkana.

Alumni Elect.—At the annual meeting of the alumni of the State Medical College, Galveston, May 30, the following officers were elected: president, Dr. Holman Taylor, Ft. Worth; vice-president, Dr. W. Wallace Ralston, Houston; secretary, Dr. Harry O. Sappington, Galveston.

Personal.—Dr. Joseph E. Dildy, Lampasas, narrowly escaped drowning while attempting to ford a swollen creek near Lampasas, June 4.——Dr. James E. Lay, Jr., Sweet Home, health officer of Lavaca County, has resigned.——Dr. E. M. Wood, Georgetown, has been appointed a member of the State Board of Medical Examiners, vice Dr. J. H. Evans, deceased.

Compulsory Vaccination.—The attorney-general has rendered an opinion, on the presentation of the question by the county attorney of Jackson County, to the effect that a local health officer has no authority to require vaccination of schoolchildren as a condition precedent to attendance at school, nor can he close the schools on failure to observe such requirement. It is held that authority to close the schools can only be exercised by the trustees when there are actual cases of disease in a school.

VIRGINIA

Trachoma in the Virginias.—Surgeon Taliaferro Clark of the United States Public Health Service, in *Public Health Reports*, June 5, reports on the survey of trachoma conducted in Virginia and West Virginia during 1913 and 1914. Inspections were made in twenty-three counties of the state, in which 20,848 persons were examined, among whom 340 cases of trachoma were found, 1.63 per cent. The survey of the mountainous sections of Virginia was completed April 29, 1914, during which ten counties in Kentucky and West Virginia were also visited, and 7,801 persons were examined. Of these, 108 had the disease, 1.38 per cent. Examinations were confined almost exclusively to the schoolchildren, as this was found to afford a very good index of the prevalence of trachoma and saved time over a house-to-house examination. An examination of state institutions shows trachoma also prevalent in counties not visited. The counties of the eastern edge appear to be free from it, a fact which is probably due to infrequent contact with infected territory. No systematic effort is being made to control the spread of trachoma over the infected territory. The necessity of action for suppression of the disease is shown by the 5.29 per cent. of marked visual damage in the total trachoma cases found during the survey of West Virginia. Recent foreign immigration was not an element in the introduction of trachoma. The negro race in the two states is practically free from the disease. Among the recommendations made by Clark are that systematic examinations should be made of all schoolchildren of the states, and the children suffering from active trachoma should be excluded from the schools and placed under medical supervision. A school nurse should be employed wherever practicable, to visit the homes of the children debarred from schools, and put into practice under the physician's directions principles of control. A campaign of education should be instituted in the infected territory through talks and distribution of printed information. Free hospitals of inexpensive construction are recommended at points convenient to groups of the most heavily infected counties. Cooperation of the mining companies should be secured so that systematic examination of miners might be made for trachoma. Improvement should be made in the sanitary condition of the rural schools.

WEST VIRGINIA

Antituberculosis Work.—Dr. Harriet B. Jones, Wheeling, director of the tuberculosis exhibit of the Anti-Tuberculosis League of West Virginia, reports that during the year she has visited 130 towns and 35 counties, has given 365 talks in schools to 37,592 pupils, has lectured 93 times at night to 17,877 adults. The tuberculosis exhibit car, in charge of Dr. Thurman Gillespy, Wheeling, has visited 133 towns and has been seen by at least 100,000. Literature was distributed from the car, in schools, at lectures, in trains and at railroad stations. The car was donated by the Baltimore and Ohio Railroad, and free transportation was given over all roads during the six months of the work. Twenty counties yet remain to be visited, and the work will begin again in the fall.

WISCONSIN

Sanatorium to Be Enlarged.—On May 22, Dr. John R. Currens, trustee of the Maple Crest Sanatorium, Two Rivers, appeared before the board, pleading the overcrowded condition of the sanatorium and the necessity of having separate wards for men and women. An appropriaiton of $3,500 was made.

Leper in Soldiers' Home.—It has been discovered by the medical staff of the Soldiers' Home, West Allis, that one of the inmates, who came to the home from Hot Springs, Ark., about two weeks ago, is suffering from leprosy, believed to have been contracted while serving in the Philippine Islands.

Personal.—Dr. and Mrs. Victor F. Marshall and son and Dr. Albert E. Rector, Appleton, sailed for Europe, June 27.——Dr. John M. Beffel, Milwaukee, has recovered from his recent illness.——Health Commissioner George C. Ruhland, Milwaukee, has appointed Drs. Leopold Schiller and Emil T. Lobedan as medical aids. Dr. Schiller has been placed in charge of the contagious diseases and Dr. Lobedan in charge of the child welfare. Dr. George R. Ernst, Wauwatosa, remains in charge of the tuberculosis division.

GENERAL

Fight Bubonic Rats.—The House of Representatives, on June 11, sanctioned an appropriation of $200,000 to kill rats and squirrels in California.

Medical Examiners Meet.—The fourteenth annual meeting of the Association of Medical Examiners will be held June 22 at Hotel Denis, Atlantic City, under the presidency of Dr. Henry Wireman Cook, Minneapolis.

American Association of Immunologists.—The first annual meeting of the American Association of Immunologists will be held in Atlantic City, at the Hotel Chelsea, Monday, June 22. A program of interest and importance has been arranged.

Bequests and Donations.—The following bequests and donations have recently been announced:

Presbyterian Hospital, Philadelphia, $1,000, by the will of Anna Claghorn.

University of North Carolina, for the construction of an athletic stadium, a donation of $25,000, by Mr. I. E. Emmerson, Baltimore.

St. Justin Hospital, Montreal, a donation of $5,000.

Public Health Day at Biennial.—June 15 was celebrated as Public Health Day at the Chicago meeting of the Federation of Women's Clubs. The program of the conference included the topics of public health, visiting nurses, the rights of childhood, work of women in tuberculosis, value of marriage certificates and the teaching of social purity. The day was under the auspices of the Chicago Medical Women's Club.

Students of Epilepsy Hold Meeting.—At the anual meeting of the National Association for the Study of Epilepsy and the Care and Treatment of Epileptics, held in Baltimore, May 25, under the presidency of Mr. William C. Graves, Chicago, about 200 physicians and laymen were present. The next annual meeting will be held in Skillman, N. J., at the New Jersey Home for Epileptics, as guests of the president of the board of managers and Dr. David F. Weeks, the superintendent. The following officers were elected: president, Dr. Albert S. Priddy, Lynchburg, Va.; vice-presidents, Drs. David F. Weeks, Skillman, N. J.: J. M. Murdoch, Polk, Pa., and Walter C. Van Nuys, Newcastle, Ind.; chairman of the executive committee, Dr. James F. Munson, Sonyea, N. Y.; and secretary-treasurer, Dr. Arthur L. Shaw, Sonyea, N. Y.

The Russell Sage Institute of Pathology.—At a meeting of the board of directors of the Russell Sage Institute of Pathology, held in New York, June 5, the following officers were elected: president, Dr. D. Bryson Delavan; vice-president, Dr. Simon Flexner; secretary, Dr. Theodore C. Janeway; treasurer, Dr. Graham Lusk. Appointments to the scientific staff were as follows: scientific director, Dr. Graham Lusk; medical director, Dr. Eugene F. Du Bois; chemist, F. C. Gephart, Ph.B.; assistant, Dr. A. L. Meyer. Dr. Lusk reported for Dr. Du Bois that 142 observations had been made on patients and on some normal controls during the past year and a half, using the respiration calorimeter established in the second medical division of the Bellevue Hospital. In certain individuals an exact agreement between the actual heat production and the heat calculated from the gaseous exchange during hourly periods was obtained for the first time in man. In the total of all experiments involving the measurement of 23,000 calories, these two methods of direct and indirect calorimetry agree both in health and disease within 1¼ per cent. The investigated cases included nine cases of typhoid during both fever and convalescence, one cretin, seven cases of exophthalmic goiter, one of splenic anemia, another with pernicious anemia, one man with acromegaly, one with hypopituitarism, one with malaria, and one with auricular fibrillation, mitral stenosis and greatly enlarged heart.

CANADA

Hospital News.—The Kingston General Hospital had 2,108 patients during the year 1913: 88 deaths and 76 births. At the Hotel Dieu Hospital the patients numbered 1,823: 62 deaths and 76 births.——The Connaught Home for Nurses has been opened at the Weston Sanatorium near Toronto.——A special building for eye, ear, nose and throat work has been opened at the London Victoria Hospital; also a ward with a roof garden for tuberculosis cases.——Vernon, B. C., has voted $5,000 to its general hospital.

Personal.—Dr. George R. McDonagh, Toronto, has returned from four months in South America.——Dr. William P. Caven, Toronto, will sail for Europe shortly.——Dr. Douglass W. Montgomery, San Francisco, while in Toronto recently, was entertained at dinner by Dr. William H. B. Aikins at the York Club.——Dr. Helen MacMurchy, Toronto, has sailed for England, where she will represent the Ontario government at the Health Conference of the Victoria League.——Dr. Robert J. Blanchard, Winnipeg, for many years chief surgeon of the Manitoba division of the Canadian Pacific Railway, has resigned and Dr. A. W. Moody appointed to the position.——Dr. Robinson of the anatomic department of the University of Toronto, acceptably filled in the lectures of Dr. Andrew W. H. Lindsay, Dalhousie University, Halifax, during the latter's illness. Dr. Lindsay was subsequently drowned in the *Empress of Ireland* disaster.

University News.—April 30 fourteen candidates, thirteen men and one woman, received the degree of M.D., C.M., from Dalhousie University, Halifax. The pathologic department is now housed in a new building erected close to the Victoria General Hospital. The faculty of medicine will occupy the old arts and science rooms when the latter enters into its new quarters.——The Dr. Copwell medical library, which was left to the Nova Scotia Medical Society and the Halifax Medical College conjointly some years ago, is now, owing to the incorporation of the medical college with Dalhousie University, the subject of litigation. The Medical Society of Nova Scotia reminded the university that they had an interest in the library, and it could not be taken over by the university without the society's consent. Hence the university has subjected the matters to the courts for a decision as to legal ownership.——The Ontario government has made a grant of $10,000 to the medical faculty of Queen's University, Kingston. Owing to the recent adoption of the five-year course, there will be required for next session a professor of biochemistry, an assistant professor of physiology and an assistant professor of bacteriology and hygiene. The grant will go toward the increased expenditure in connection with these appointments.——The corporation of McGill University, Montreal, has adopted a regulation requiring all students to produce a certificate of vaccination before entering the university.——The medical department of the Western University, London, Ont., has been granted $10,000 by the Ontario government. Twenty-three were graduated from the department at the close of the present session, Dr. C. C. Cornish, Ingersoll, Ont., being the gold medalist. A professor of physics and a professor of physiology is to be appointed, which will give six full-time professors.——Twenty-five students have been in attendance the past session in the premedical course at the University of Alberta. Next year a two-year course will be given.

LONDON LETTER

LONDON, May 29, 1914.

Adami on Medical Education in Canada

John George Adami, who is now in London, has been publicly awarded the Fothergillian Medal by the Medical Society of London for his distinguished services to pathology. In a press interview he has given his views on medical education in Canada. He regards the outlook as unquestionably hopeful as is evidenced, for instance, in the recent opening of the magnificent hospital at Toronto. This, with its splendid attached laboratories for pathology and pathologic chemistry, is now, he considers, the most up-to-date hospital in the world. It has been possible, by the cooperation of the state, the city and the university, to secure adequate funds, and in Toronto, as in other cities in Canada and the United States, the fact that it has been practicable to start from rock bottom has been a great advantage. The great weakness in Canada, he thinks, is its terrible system of preliminary education, which is due partly to the country having adopted "the unfortunate American ideal of the class system." The democratization of education results in the bright boys of a class idling eight months of the year, and in consequence the ordinary American or Canadian boy is two or three years behind when he comes up to the university. His English is defective, his general knowledge is miserable, and he cannot express himself. Again we have the appalling predominance of women teachers. Owing to the opportunities in the country only the poorer type of man is attracted into teaching and the bulk of preuniversity work is done by women who for the most part are farmers' daughters. So much is this the case that the technical school journals use the word "she" instead of "he" in referring to teachers. A vicious circle has been started, for the people, finding that their children benefit little either in learning or in general character from the schools, refuse to spend the money necessary to attract good men into the service. The evils of the school training are, however, partly corrected by the individualism of the students when they come to the universities. When one compares Canadian medical education with that of the United States we have one great advantage, says Adami. We have retained the English traditions of allowing the students to walk the hospitals—Sir William Osler succeeded in introducing it into America in the Johns Hopkins Hospital—and as a result of the Canadian method we find Canadian doctors holding a large number of very important positions in the United States. Another difference between ourselves and the States is that they are inclined to think that a student should take a degree in arts before starting medicine. This tends to make a man terribly academic by the consequent length of the curriculum, and thus to unfit him for work as a general practitioner. In Canada we aim rather at giving our men all that is necessary in the preliminary sciences by using medical examples. For example, we rather teach the physics of lenses by means of the ophthalmoscope, and some of the elements of sound by the stethoscope, and we look to the schools to get men familiar with the bare elements of the preliminary sciences.

The British Medical Association and the Issue to the Public of Books on Medical Subjects

The scandal created by the publication of "The Family Encyclopaedia of Medicine" has been described in a previous letter to The Journal. It must be borne in mind that the professional rule against advertising is much more stringent in this country than in America. A physician is forbidden to bring himself before the public in any way calculated to attract patients. The council of the British Medical Association has issued the following rules: 1. The publication of a book to the public on a subject of general interest—such, for instance, as dietetics—by a medical man is not a transgression of any definite rules of medical ethics if the object of the publication is to inform the public and not to advertise the medical man. 2. Such book may be advertised in the lay press, but the propriety of this would depend on the nature of the advertisement, which should conform to certain recognized principles. 3. There can be no objection to signing the preface to a book if the object of the publication is to inform the public and not to advertise the medical man, but it is desirable that his address should not be added. 4. The publication of a book to the public on medical subjects which contains a large number of prescriptions in common language is highly dangerous to the public and should not be countenanced.

Scientist's Novel Claim

Sir Ronald Ross, K.C.B., F.R.S., the well-known discoverer of the fact that malaria is conveyed by mosquitoes has forwarded to the Chancellor of the Exchequer for submission by him to Parliament a petition setting forth his claims for a grant or pension. He says that he has adopted the precedent of Jenner in order to bring to a head the whole question of the treatment of scientific men in this country. Edward Jenner was a practicing physician and when he discovered vaccination against small-pox he lost most of his practice in consequence of the time spent in the investigation. He accordingly petitioned Parliament which gave him for compensation $50,000 in 1802 and $100,000 in 1807. At present the only grants made by Parliament in consequence of scientific or literary eminence are small pensions varying from $100 to $1,000 a year. These partake somewhat of the nature of charity, as they are granted to persons who have benefited humanity by their work and are in needy circumstances. They are also granted to their widows or children in similar circumstances. Sir Ronald Ross says that the principle here is wrong, not to say ignoble. It is not a question of public charity but public indebtedness. It is not fair that persons should suffer pecuniarily for the advantages which they confer on the world or on their nation. Only in certain branches of science do discoveries result in pecuniary gain, as in the smaller clinical observations which increase the practice of physicians. The greatest discoveries, which determine the germs which cause disease or the methods by which they are carried from man to man, lead to no pecuniary reward, whatever, yet they are just the ones that are most important to the public. Sir Ronald's action is being widely discussed in scientific and parliamentary circles as the principle on which he bases his claim is capable of wide application to all forms of scientific, literary and artistic inventiveness. He suggests that a standing fund and a standing committee should be appointed to investigate claims, the settlement of which he does not think would require more than $100,000 per annum.

PARIS LETTER

Paris, May 29, 1914.

Adrenal Virilism

At the session of the Académie de médecine, May 26, Dr. Tuffier, *agrégé* and surgeon of the hospitals of Paris, made an interesting communication on the subject of suprarenal virilism: that is to say, organic disturbances of development, characterized either by precocious virility in the infant, or by the masculine aspect which a woman may acquire, even after the menopause, under the influence of a tumor of the suprarenal gland. Tuffier had the privilege of observing an example of the last variety in a woman 62 years of age, who had come under his supervision through copious metrorrhagias. The examination showed a voluminous fibroma; but since the urine contained 70 gm. of sugar to the liter, the wisdom of an operation was doubtful. At the first examination, Tuffier was struck only by the extraordinary general development of the hair of the various parts of the body. A month later, after an antiglycosuric treatment, the patient returned to his care, having only 6 gm. of sugar, and being in a favorable condition for an operation. Less scrupulously shaved than at the former visit, she had a heavy black beard and mustache. Her face was red and swollen; there was a slight exophthalmos and the frontoparietal baldness which is almost exclusively masculine; the limbs were very muscular, and the proportions were altogether masculine. The examination of the external genital organs showed a hypertrophy of the clitoris, which measured about 4 cm., and covered a decidedly developed prepuce. In questioning the patient, it was discovered that these phenomena had developed only since the menopause. The habits of the subject had undergone a like change; she cared for nothing but heavy manual labor—plowing, digging—which did not tire her in the least.

The operation showed, perhaps, the reason for this morphologic curiosity. For, in the course of the laparotomy, the examination of the suprarenal region brought to view a bilateral mass overhanging the kidneys, of a fibrolipomatous consistency. The left ovary had atrophied; on the right ovary there was a tumor the size of a large walnut, soft, hemorrhagic, without vegetations or cysts, and of a sort which Tuffier had never seen before. The uterus was neither fibromatous nor sclerotic, but simply in a state of pure muscular hypertrophy.

This symptomatic ensemble, which was known to the ancients, corresponds to the type called by Apert "hirsutism," by Gilbert Ballet and his pupil Gallais "suprarenal virility." It is seen particularly in female infants, and the symptoms are remarkable. This hyperfunctioning of the suprarenal gland manifests itself differently according to the age of the sufferer. If it hastens the growth of infants to abnormal proportions, it acts quite otherwise in the case of adults, particularly after the menopause, when the metabolism can affect only certain organs, and so provokes only hypertrichosis, hypersthenia and hypertrophy of the genitals.

These signs of virilism should suggest the possibility of a suprarenal tumor, for which an early operation may bring happy results.

Antityphoid Vaccination

The prefect of the Department of the Seine, invited by the Minister of the Interior to spread information about antityphoid vaccine and to facilitate its use, has just informed the doctors of his department by circular that he can furnish them with doses of vaccine if they need them. From the appearance of the first case of typhoid fever, if they think it best to vaccinate, they may get the vaccine either by addressing a request for it directly to the Laboratoire d'hygiène de la Ville de Paris, or by writing their request on the same card which is used to declare cases of contagious diseases.

Donation for Medical Museum at Lyons

The Faculté de médecine de Lyon is authorized to accept a donation made by Dr. Lacassagne, a former professor, of a sum of which the yearly interest, 450 francs ($150), shall be devoted to the use and development of the Musée historique de la médecine et de la pharmacie, built by the Faculté mixte de la médecine et de la pharmacie de Lyon.

BERLIN LETTER

BERLIN, May 22, 1914.

Rachitis and Overcrowding

The well-known Berlin pathologist, von Hansemann, *several years ago declared rachitis* to be a house disease caused by bad air and lack of exercise. Although this in no way indicates the essential cause, the investigations undertaken in this direction show more and more the importance of this view. Dr. George Levy, the vaccinator, has a very interesting article regarding this subject in the *Archiv für soziale Hygiene*. In 1,000 vaccinated children only 2.2 per cent. were found free from rachitis. The distribution of the illness and its severity are parallel to the density of the population in the respective localities in which the cases originated. The smallest number of cases was found in the homes of three rooms; 350 families who lived in two rooms, living-room and kitchen, and housing from two to thirteen persons had 350 rachitic vaccinated children. If these families lived in groups of three in the two rooms, there would be 25 per cent. *medium and* 7.3 per cent. very severe cases of rachitis. In groups of four, 35 per cent. and 5.9 per cent. severe; of six, 62 per cent.; of seven, 57 per cent. moderate, and 19 per cent. severe, and lastly of ten—here the figures are unduly small—66 and 17 per cent. If these figures are written under one another, it is distinctly seen how the frequency and severity of the illness rises with the overcrowding.

Annual Meeting of Neurologists and Alienists

At the annual meeting held at Lübeck, May 9, of the neurologists and alienists of northwestern Germany, general papers were read pertaining to the salvarsan therapy of syphilogenous nervous diseases, its dangers and possible complications.

EFFECT OF NEOSALVARSAN INJECTED INTO NERVOUS SYSTEM

The most interesting report was that by Dr. Jacob and Professor Weygandt of the large insane asylum, Hamburg (Friedrichsberg). Using monkeys for their experiments, they studied the pathologic changes in the nervous system that might result from intraspinal injections of neosalvarsan. They used a solution of 0.15 c.c. neosalvarsan in 100 c.c. 0.4 per cent. sodium chlorid solution.

Of this solution, one monkey received 1 c.c. intraspinally; two, 2 c.c. each, one, 0.4 c.c. and one, 0.2 c.c., the corresponding amount of fluid having been previously removed from the spinal canal. The first animal, with 3 c.c. showed no clinical symptoms, was well, and thirteen days later was killed. The macroscopic examination of the nervous system was negative. The second monkey (2 c.c.) killed ten days after the injection, showed neither clinical *symptoms nor macroscopic* changes in the nervous system. The third monkey (2 c.c.), however, expired the night following the experiment and the fourth animal (1 c.c.) became totally paralyzed two days after the injection (in the hind legs). It was killed seven days after the injection. The macroscopic findings were negative. The animal that received 0.4 c.c. showed paresis two days later and died three days later. The one that received 0.2 c.c. died two days after the injection.

Microscopic changes in the nervous system could be detected in every one of the animals, even in those that gave no clinical symptoms. The parenchymatous changes in the nervous system were very marked, and in the monkey that received 1 c.c., focal lesions were found even in the medulla. The lumbar portion of the spinal cord was affected most.

Two monkeys received each 2 c.c. of the same neosalvarsan solution, intracerebrally and subdurally. One succumbed three days after the experiment; the other developed left hemiparesis the next day, and two days afterward had severe epileptic attacks. The paralytic phenomena and the epileptic fits increased in severity during the following days, and on the sixth day the animal died. In this animal a hemorrhage was found at the place of the injection, and pathologic *changes in the brain* and *spinal* cord. The other animal showed such changes only at the place of the injection. Finally, two more monkeys were injected with a 0.15:300 solution of neosalvarsan. The doses were 0.6 c.c. subdurally, and 0.4 c.c. intraspinally. No clinical symptoms resulted and the microscopic examination of the animals, killed, respectively, seven and twenty-four days later showed an intact nervous system.

The conclusions Jacob and Weygandt draw from their experiments is that neosalvarsan in very concentrated solutions is dangerous, but in weak solutions is practically harmless.

Marriages

P. A. SURG. ROBERT A. HERRING, U. S. P. H. S., to Miss Emily Humbar White, at the Marine Hospital, New Orleans, June 4.

P. A. SURG. JASPER VICTOR HOWARD, U. S. N., to Miss Prudence Estelle Wyman of Olympia, Wash., May 28.

SIDNEY HERMAN ADLER, M.D., New York City, to Miss Elsie Tobias of Far Rockaway, L. I., N. Y., June 10.

CAPT. WILLIAM A. WICKLINE, M. C., U. S. A., to Miss Grace Gooding of Washington, D. C., May 5.

JERE LAWRENCE CROOK, M.D., Jackson, Tenn., to Miss Millian Cooke Green of Elk Hill, Va., June 17.

BUFORD COSBY BIRD, M.D., Colquitt, Ga., to Miss Chevis Evans Strong of Montgomery, Ala., June 17.

LEWIS A. BUCHMAN, M.D., Canton, Ohio, to Miss Molly Jane Reed of North Industry, Ohio, June 1.

WILLIAM LEMUEL BENEDICT, M.D., Fresno, Cal., to Miss Edith H. Betz of Adrian, Mich., June 2.

JOHN PARKER LOUDON, M.D., to Miss Florence Ellen Jones, both of North Yakima, Wash., June 4.

LEWIS JOHN POLLOCK, M.D., Chicago, to Miss Katherine Percy of Galesburg, Ill., June 6.

JAMES B. LOWRY, M.D., Atlanta, Ga., to Miss Mertie I. Gracy of Lakeland, Fla., May 11.

HOWARD RISK, M.D., Waverly, Ia., to Miss Letha Margaret Kint of Oelwein, Iowa, June 3.

H. H. HORNBECK, M.D., to Miss Ora Stanford, both of Kingston, Okla., May 23.

ARNOLD GARLITZ, M.D., St. Louis, to Miss Elsie Sureth of Wilmette, Ill., June 2.

Deaths

William F. Robeson, M.D. University of Pennsylvania, Philadelphia, 1885; a member of the Medical Society of the State of Pennsylvania; and an ophthalmologist of high rank; formerly president of the Allegheny County Medical Association; ophthalmic surgeon to the Pittsburgh Eye and Ear Hospital, Mercy Hospital, Children's Hospital and Pittsburgh Hospital; ophthalmologist to the Western Pennsylvania Institution for the Blind; oculist for the Pennsylvania, Baltimore and Ohio, and Pittsburgh and Lake Erie railroads; formerly surgeon of the Eighteenth Infantry, N.G., Pa.; died at his home in Pittsburgh, June 3, aged 50.

James Augustus Blake, M.D. Albany, N. Y., Medical College, 1868; College of Physicians and Surgeons in the city of New York, 1869; of Brooklyn; a member of the Medical Society of the State of New York; and a specialist in diseases of the eye, ear, nose and throat; formerly a member of the staff of Charity Hospital, and Manhattan Eye and Ear Hospital, New York City, and the Methodist Episcopal Hospital, Bedford Dispensary and Hospital, and Brooklyn Eye and Ear Hospital; died at his home in Brooklyn, June 9, from cerebral hemorrhage, aged 71.

Dan Millikin, M.D. Miami Medical College, Cincinnati, 1875; a member and once president of the Ohio State Medical Association; formerly professor of materia medica and medical jurisprudence in his Alma Mater; prominent as a physician and writer of Ohio; president of the Hamilton Board of Education; died at his home in Hamilton, June 5, from arteriosclerosis, aged 69.

D. Winton Dunn, M.D. American Medical College, Eclectic, St. Louis, 1890; formerly mayor of Duquoin, Ill.; while alone in his office in Duquoin, June 6, was shot by a coal miner who owed him a bill, and whose child he is said to have refused to treat on that account. Dr. Dunn was taken to St. Louis on a special train, but died from his injuries, June 7, aged 62.

William C. Gilmour, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1882; of Oakland, Ore.; died at his home in that city, May 9, from heart disease, aged 54.

Leland Madden Baker, M.D. Boston University School of Medicine, 1894; died at his home in Lynn, Mass., May 27, from nephritis, aged 45.

George Dallas Nutt, M.D. University of Pennsylvania, Philadelphia, 1869; a prominent citizen of Williamsport, Pa.; one of the organizers of the Williamsport Hospital, and of the Williamsport Private Hospital; for many years dean of the post-graduate school connected with the institution; a Fellow of the American Medical Association; died at his home, May 30, aged 69. The Lycoming County Medical Society at a special meeting, decided to take action on the death of Dr. Nutt, and to attend his funeral on foot in a body.

Amos Lawrence Mason, M.D. Harvard Medical School, 1872; a member of the Massachusetts Medical Society; for twenty years senior physician at the Boston City Hospital; formerly assistant professor, and professor in his Alma Mater; an authority on contagious diseases; and one of the most prominent practitioners of Boston; died suddenly at Menand's, near Albany, N. Y., June 5, from heart disease, aged 72.

Burchard H. Roark, M.D. Rush Medical College, 1903; a Fellow of the American Medical Association, and county physician of Spokane, Wash.; a veteran of the Spanish-American War; while attempting to cross the track of an electric railway near Coeur d'Alene, Ida., in his motor car, May 30, was struck by a train and instantly killed, aged 37.

William L. Grant, M.D. Jefferson Medical College, 1856; surgeon of volunteers during the Civil War; and one of the members of the Wheeling Convention which laid the plans for the State of West Virginia, and also a member of the second convention, which completed those plans; died at his home in Grafton, W. Va., June 2, aged 92.

Francis Bishop Harrington, M.D. Harvard Medical School, 1881; a Fellow of the American Medical Association and American Surgical Association; for many years chief surgeon to the Massachusetts General Hospital; lecturer on surgery at Harvard Medical School; died at his home in Brookline, Mass., June 8, aged 60.

Eugene A. Wheeler, M.D. Denver College of Medicine, 1893; a Fellow of the American Medical Association; surgeon to the L. V. and T. Railroad, and to St. Mary's Hospital, Goldfield, Nev., aged 47; while returning from a meeting in Tonopah, Nev., June 9, was instantly killed by the overturning of his automobile.

Frank Delmont Humphrey, M.D. University of Iowa College of Homeopathic Medicine, Iowa City, 1891; died at his home in Baker, Oregon, May 19, from nephritis, aged 50.

William Justus Jones, M.D. McGill University, Montreal, 1856; one of the oldest and best-known practitioners of Ontario; died at his home in Prescott, May 19, aged 81.

Battle Clark, M.D. Physio-Medical College of Indiana, Indianapolis, 1893; died at his home in New Haven, Ind., May 28, from malignant disease, aged 60.

Robert R. Norris, M.D. University of Maryland, Baltimore, 1878; for thirty years a practitioner at Parkton, Md.; died at his home in that city, May 23, aged 63.

Bernard St. Elmo Ryan, M.D. University of the South Sewanee, Tenn., 1908; died at his home in Philomont, Va., May 25, from heart disease, aged 38.

John A. Jeffries (license, Illinois, 1878). For half a century a practitioner of Rinard, Ill.; died at his home in St. Louis, May 26, aged 80.

George R. Snyder, M.D. Jenner Medical College, Chicago, 1907; of New York City; died in a hospital in San Antonio, Texas, May 25, aged 40.

Charles Murray, M.D. Philadelphia University of Medicine and Surgery, 1864; died at his home in Edwards, N. Y., May 25, aged 82.

Emma J. Roberts, M.D. Minneapolis College of Physicians and Surgeons, 1901; died at her home in Chicago, May 24, aged 48.

William H. Ribble, M.D. New York University, New York City, 1859; died at his home in Wytheville, Va., May 21, aged 79.

Elisha L. Day, M.D. Tulane University, New Orleans, 1872; died at his home in Dallas, Texas, May 24, aged 63.

Edward Joseph O'Brien, M.D. Rush Medical College, 1906; of Chicago; died in West Baden, Ind., June 5, aged 34.

John O. Eberhard, M.D. Jefferson Medical College, 1873; died at his home in Philadelphia, May 29, aged 63.

Frank Love Kiley, M.D. Jefferson Medical College, 1893; of Philadelphia; died about May 22, aged 45.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

POLLUTING THE STREAM AT ITS SOURCE

From day to day, the physician is a recipient, either willing or unwilling, according to his time and ability, of a free postgraduate course in therapeutics. First in importance comes the detail man with his well-memorized "story." Then the doctor is invited to hang on his office walls a host of multicolored advertising posters. He is deluged with enough advertising blotters to absorb an ocean of ink. Through the mails come pamphlets, packages and writeups by men who were failures as physicians. When at last the doctor dies, the unwitting distributors of the literature continue to deluge his home and family with drugs and advertisements until time has worn his name from every medical directory and distributing agent's list.

Physicians, of course, know all this. They may not know, however, that the student, before his graduation, is initiated into this proprietary educational system. It is true that this early appeal is also diminishing. But as proof that a few manufacturers still continue the methods, witness the following correspondence:

"*To the Editor:*—I enclose two letters which I have received recently. They are the most impudent of the many with which I have been deluged. It seems that their scheme of offering the president or secretary of the graduating class a commission is successful sometimes, for several of these patent medicine houses have written as an encouragement, that at such and such a medical school the president had cleared $40 on the proposition, etc. From this, and from the cool effrontery with which these houses write, it seems that the students of a number of medical schools are not enlightened on the subject of proprietary medicines. This is a serious reflection on their teachers and emphasizes the importance of teaching the social and ethical, as well as the scientific aspects of medicine. There is very little of such instruction at present.

"Ernst Boas,
"Secretary Senior Class, Columbia University, College of Physicians and Surgeons."

Enclosed with the foregoing were the following letters:

"Secretary Senior Class, Dept. of Medicine.
"Dear Doctor:

"It has been our practice for a great many years, in January, to furnish all Seniors and members of graduating medical classes with one of our regular $1.00 Outfits, containing an *improved oil Nebulizer,* a *Pipet* and *bottle of Pineoleum* (formula in upper left hand corner of this letter-head) without cost and *with our compliments.*

"It is also our practice to pay each Secretary or President (whoever makes the distribution) five cents for each receipt furnished us, giving the full name and home address of each member of the class and the faculty, thereby showing that he has delivered to each, one of our Outfits. We ship the goods by prepaid express to the College and when the receipts showing the deliveries, have been returned we forward our check as per the above.

"If you will kindly give us an immediate reply (in the enclosed stamped envelope) indicating whether or not you will attend to the matter for us and informing us of the number of men in the graduating class and faculty, we will at once take up the matter with you further.

"Very truly yours,
"The Pineoleum Company."

"Secretary, Senior Class, Columbia University College of Physicians and Surgeons.
"Dear Doctor:

"It is our intention to present each of the members of the senior class with a copy of our 400 page cloth bound library edition price-list containing a section on clinical suggestion which should make it of interest and value to each of them. With the list we shall include a sample copy of the *American Journal of Clinical Medicine* and our recent issue of 'Helpful Hints for the Busy Doctor,' both of which are of undoubted interest and value.

"So that we may continue mailing our 'Helpful Hints' from time to time, we desire the names and permanent home addresses of each member of the senior class and if you will furnish us with this information we shall present you or the student whom you may select to compile the list and distribute the samples, a 12-vial emergency case filled with active principles suitable for this class of practice.

"On receipt of the list of names we shall forward the above mentioned printed matter by prepaid delivery to either yourself or the student appointed.

"Assuring you of our appreciation of any courtesy you may show us, and of our desire to reciprocate in any way possible, we are, with regards,

"Very truly yours,

"FRANK B. KIRBY, M.D.,

"*The Abbott Alkaloidal Company*, Department of Sales.

"P. S. We have interesting proposition whereby a live-wire student, preferably in the senior class, can make some money with but little effort and with no loss of time."

The way to get rid of these attempts to debauch the young graduate is indicated in our correspondent's words: "It seems that the students of a number of medical schools are not enlightened on the subject of proprietary medicines." There is need in every school not only of an intensive course in what is worthy and efficient but also of demonstrations and lectures on proprietary methods and "What Not To Prescribe."

CONVICTIONS UNDER THE FOOD AND DRUGS ACT

BEEF, WINE AND COCA

Warren Sutliff, G. W. Case, J. Weinkauff and Ensley J. Case, who did business under the firm name of Sutliff, Case & Co., Peoria, Illinois, shipped in interstate commerce a quantity of so-called beef, wine and coca. According to the label, the product contained alcohol 15 per cent. and cocain 1/5 of a grain to each fluid ounce. When analyzed by the government chemists, the stuff was found to contain not 15 per cent. of alcohol, but 23.75 per cent. It was, accordingly, declared misbranded. The defendants pleaded guilty to the charge and were fined $10 and costs.—[*Notice of Judgment No. 2213.*]

MALT NUTRINE

The Anheuser-Busch Brewing Association sold, in violation of the Food and Drugs Act, a quantity of "Malt Nutrine," which the government officials declared was misbranded. The label bore such claims as:

> "Alterative, Nutritive, Tonic, Strengthening, Invigorating, Sedative."
> "A Non-intoxicant Sparkling Concentrated Liquid Extract of Malt and Hops."
> "Makes Blood and tissue. Aids digestion. Lends strength to the weak. Triumphs over disease. Nourishes the convalescent."
> "Rests the brain and quiets the nerves. It is invaluable to nursing mothers. Nothing like it for teething children. Enriches the blood and builds up the system."
> "A concentrated extract of Malt of Acknowledged Merit."

The label was declared misleading and false in that the claim "highly concentrated extract of malt" signified that the product was a pure extract of malt concentrated, when analysis proved that it was not, but consisted of other ingredients than malt, to wit: Alcohol, 1.6 per cent., and extractive matters from hops. The company pleaded guilty and a fine of $50 was imposed.—[*Notice of Judgment No. 2310.*]

MANADNOCK LITHIA SPRING WATER

S. A. Scammon of Temple, N. H., shipped in interstate commerce a quantity of Manadnock Lithia Spring Water. Some of the claims made for this product were:

> "The most wonderful natural Lithia Spring water now known in the world."
> "Recommended for Gout, Dyspepsia, Rheumatism, Eczema, Sugar Diabetes, Bright's Disease, Gall Stones; also reduces temperature in all fevers; and all diseases of the kidneys, asthma, etc."
> "As beautifier of the complexion, it has no equal."

This so-called lithia water was declared misbranded, as it contained only an unweighable trace of lithium and not enough to warrant the water being classed as a lithia water. Scammon entered a plea of *nolo contendere* and was fined $15.—[*Notice of Judgment No. 2814.*]

BUCKHORN LITHIA WATER

A quantity of "Buckhorn Lithia Water" was shipped by a company of the same name from Henderson, N. C., into Georgia. The labels on this product contained the following statements:

> "This water has the highest scientific endorsement as a cure for catarrh of stomach or bowels, constipation and indigestion."
> "Beneficial in all fevers, especially typhoid."
> "It gives the quickest relief in all uric acid troubles, thick or discolored urine, stone in bladder, pain in urinating."
> "It cures kidney and bladder troubles, sciatica, rheumatism and gout."

The water was declared misbranded by the federal authorities, first, because of the false statements regarding curative effect, and, second, because while called a lithia water, it did not in fact contain enough lithium to give the therapeutic effect of lithia water. The company pleaded guilty and the court suspended sentence on payment of costs.—[*Notice of Judgment No. 2709.*]

SUN-RAY SPARKING WATER

"Sun-Ray Sparking" was a water claimed to be "the world's purest spring water," marketed by the Sun-Ray Water Company of Ellenville, N. Y. The label bore a picture of a stream of water flowing out of a tunnel, and under the picture was the description, "Famous Sun-Ray Spring Tunnel, Ellenville, N. Y." This water was declared misbranded by the federal authorities in that the label indicated that the product was a natural spring water. As a matter of fact, it was water to which sodium chlorid (common salt), sodium bicarbonate (baking soda), and carbon dioxid (carbonic acid gas) had been added. The Sun-Ray Water Company pleaded guilty and was fined $50.—[*Notice of Judgment No. 2481.*]

HICCURA MINERAL WATER

P. F. Panabaker of Omaha, Nebraska, trading under the name "Hiccura Mineral Water Company," shipped in interstate commerce, a quantity of mineral water which the federal authorities declared misbranded. The following claims were made for the stuff:

> "Natural Mineral Water."
> 'Pure Natural Remedy."
> "Hiccura Mineral Water is the strongest and most perfect of Natural Waters."

The federal authorities declared the water misbranded in that the "Hiccura Mineral Water" was not a "natural" water, but an artificial mineral water, containing ferric sulphate, 84 grams per liter, and aluminium sulphate 21 grams per liter. Panabaker pleaded guilty and was fined $15 and costs. [*Notice of Judgment No. 2380.*]

Association News

CLINICAL INFORMATION BUREAU IN NEW YORK

Fellows of the American Medical Association and other visiting physicians will be cordially welcomed at the clinics which are daily held in the hospitals of New York City. An information bureau has been established in the New York Academy of Medicine. The details of about fifty operative clinics are posted there daily.

Propaganda in the Public Schools against Medical Frauds.—A unique method of propaganda against patent medicines and medical frauds has been inaugurated in the high schools at La Fayette, Ind. An effort is being made to inform the pupils, and through them the families from which they come, regarding various medical frauds. The plan was originated by Professor Pierson of the department of physiology. Pupils were requested to bring to school all newspaper advertisements of patent medicines and "quack" doctors. The iniquity of this form of advertising and the absurdity of the claims of the patent-medicine men and the "quack" doctors were explained to them. Great enthusiasm was shown and literature concerning the subject was gathered by the students in physicians' offices and elsewhere. Special attention was drawn to the dangers of medicines containing habit-forming drugs. This novel method should be highly effective in teaching the public the evils of patent medicine and quackery.—Correspondence, *Indiana State Med. Jour.*

Correspondence

Sudden Blanching of the Hair

To the Editor:—In an editorial in The Journal, May 30, 1914, p. 1726, on the growth and color changes of the hair, sudden blanching of the hair is put down as "mythical," and Stieda's views are accepted that the hairs turn gray only as new hairs without pigment grow. "No sudden mutations are found when accurate observations are instituted."

Stieda's reasoning to my mind is not convincing, and I believe that with our ignorance of the factors controlling pigment formation in the skin we are in no position to dogmatize on this subject—certainly in no position to cast aside as unreliable cases because they do not square with our present notions. Most of the recorded cases of this sort are old, but we are not the first generation of reliable observers, and it does not require modern instruments of precision to make a diagnosis of gray hair. I would offer in evidence on this point one modern case, which so far as I know has not appeared in the literature of this subject. It is the following:

> "Perhaps you will allow me to digress for a moment to mention to you a very remarkable illustration of the latter fact—increased pigmentation in the vicinity of its diminution. I have mentioned the case elsewhere, but it will probably be new to you. It is that of a man who had traumatic meningeal hemorrhage over the left hemisphere. As a result of this, during the three days he lived after the injury, the right, opposite half of the hair of his head and of his brown moustache and beard became blanched so as to be almost white. The change was watched during life and carefully noted after death. It was like that which has been described as the result of profound emotion, but it was due here to a physical agency. It can only be explained by assuming that the disordered innervation so changed the secretion at the roots of the hair as to produce a material capable of ascending the hairs and discharging their pigment. But after death we noticed another thing, which leads me to mention the case. The very gray, almost white, right half of the beard was separated from the brown left half by a narrow vertical line, or narrow zone, in the middle line, in which the hair had become almost black. Apparently where the disordered influence ceased in its extreme degree, at the blending of the innervation of the two sides, a change in the pigmentary process had occurred of the opposite character. Mysterious as the fact is, and perhaps impossible to explain, it illustrates the close relation between the plus and the minus in pigmentary processes." (Clinical Lectures, by Sir William Gowers, M.D., F.R.S., 1904, p. 153.)

One positive fact of this sort will of course knock down a whole theory based on negative reasoning, and I do not believe that this case can be brushed aside as a myth. Sir William Gowers is not an ancient; he belongs in the forefront of modern neurology—certainly a field whose workers are trained to guard against deceptions—and he has standing as a clinical observer.

"The change was watched during life and carefully noted after death"; and not only that, but hyperpigmentation of bordering hair occurred.

In the face of this observation—leaving all others out of consideration—I believe we are compelled to accept the fact that sudden blanching of the hair may occur. And I am aware of nothing that makes the acceptance of this observation a shock to our knowledge of skin pigment. As a matter of fact, sudden macroscopic changes in the skin's pigment—and the hair's pigment is the same—are not excessively rare observations. As recently as the May meeting, this year, of the American Dermatological Association, Hazen of Washington referred to the sudden appearance of patches of leukoderma in a negro ill in hospital under constant observation; in this case patches of white skin appeared on the abdomen within thirty-six hours. Carmichael mentioned a similar case. How such a change could occur we are at a total loss to explain; but that has nothing to do with the fact.

William Allen Pusey, M.D., Chicago.

Preventive Inoculations for Typhoid

To the Editor:—In the Current Comment on "Typhoid Prevention among Seamen" (The Journal, May 16, 1914, p. 1563), the following statement is made: "So far, preventive inoculations for typhoid have been used only in military and naval circles and in hospital work among physicians and nurses. The results have been so favorable that it would seem to be time to secure the introduction of the practice of typhoid immunization to the public." It may interest you to know that the North Carolina State Board of Health has been providing free typhoid vaccine since early in January of this year, and that as whole-time county health officer for Sampson County, I have since January 16 given free preventive inoculation to 258 persons, mostly white, with a few negroes, both sexes, ages ranging from 4 to 61 years, from almost every walk in life. I have many engagements to continue the work on through the summer, and at the end of the year I expect to have some valuable data on the subject. I am not writing this as a criticism, but simply to report the activity going on in an obscure rural county.

G. M. Cooper, M.D., Clinton, N. C.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

SPAHLINGER TREATMENT OF TUBERCULOSIS

To the Editor:—Do you know anything about the new cure for tuberculosis as described by Henry Spahlinger to the Academy of Medicine, Paris, April 28, to be a mixture of antigens and ferments?

W. W. Dill, M.D., Redlands, Cal.

Answer.—The *Bulletin de l'Académie de médecine*, May 4, 1914, gives the following statement:

"PRESENTATION OF MANUSCRIPTS AND PRINTED WORKS

"M. Letulle: I have the honor to present a preliminary note entitled 'The Treatment of Tuberculosis by the Method of Henry Spahlinger,' addressed to the academy by Dr. Edmond Lardy of Geneva, Dr. Colbeck, physician of the Hospital of the City of London for Diseases of the Chest, and Dr. L. Williams, physician of the French hospital in London.

"The method consists of a series of intramuscular injections of a combination of tuberculous antigens and ferments. This specific treatment is reinforced by an adjuvant treatment consisting of ferments combined with lipoids which are administered intramuscularly or intravenously. In fifty-four cases of pulmonary tuberculosis, all of the open variety treated for some months by this method, seventeen at the present time have shown marked amelioration. The signs of ulceration have disappeared and bacilli no longer exist in the sputum and there is continuous apyrexia.

"Before treating human tuberculosis, H. Spahlinger had, furthermore, obtained remarkable success experimentally on tuberculous guinea-pigs. More than twenty recoveries led him to make his first trials on man. (Assigned to M. Letulle for examination.)"

The statement given in the preceding quotation must be regarded merely as the claims of the author of the treatment.—Ed.

RAYMOND'S PECTORAL PLASTERS—SETON FOR MIGRAINE—ACTION OF ACETANILID, ANTIPYRIN AND PHENACETIN—SCOPOLAMIN ADDICTION

To the Editor:—1. Please inform me as to the composition or therapeutic action, if any, possessed by Raymond's Pectoral Plasters, which are "guaranteed to cure" whooping-cough. They are made by Raymond & Co., 200 Williams Street, New York City. Has it ever been investigated by The Journal's Propaganda for Reform? Please give some information on this "cure" if you can do so, as it is being exploited in this locality not only by druggists, but by physicians as well.

2. What does Osler really mean in his closing statement relative to the treatment of migraine, viz: "And lastly, in obstinate cases, an ordinary tape seton may be inserted through the skin at the back of the neck, to be worn for three months, a plan of treatment which has the strongest possible recommendation from Mr. Whitehead of Manchester (Osler: Practice of Medicine, D. Appleton & Co., Ed. 7, 1911, p. 1068).

Would there not be serious danger of infection or inflammation from leaving the seton in place so long? Is this a safe procedure to try in such cases?

3. Is there any real difference in the action of acetanilid, antipyrin and phenacetin on the central nervous system, other than a difference in the intensity of their action?

4. Is there much danger of acquiring a habit for hyoscin where the drug is being administered continually in doses of from 3/100 to 1/20 grain daily? What is the danger compared with equivalent doses of morphin administered to a male patient 68 years old?

Chester Demaree, M.D., Trafalgar, Ind.

Answer.—1. We have no information as to the composition and action of Raymond's Pectoral Plasters. The advertising matter in our files shows that the plasters are fraudulently exploited. For further information regarding this nostrum, see "Nostrums and Quackery," p. 689, or The Journal, June 3, 1911, p. 1671, under the head of "Press Clippings and Nostrum Enterprise."

2. We must take the quotation to mean what it says. The introduction of a seton was formerly much used for the purpose of exciting a lasting counterirritation. The seton is applied by drawirg a single large thread or a skein of threads through an opening made in the skin. There is, of course, some danger of infection in making such a wound, but if care be taken to have the materials aseptic, the danger of absorption of toxins or spread of the infection would be comparatively slight. The method is, however, scarcely to be recommended, and we notice that Osler has omitted all reference to it from the eighth edition, 1912, of his work on the Practice of Medicine.

3. No.

4. So far as we know, an addiction to scopolamin (hyoscin) has not been observed to any considerable extent. The danger of inducing such a habit would be far less than with morphin. Scopolamin acts more by depressing the motor area than by its effect on the sensory portion of the brain.

REFERENCES TO ABLATIO PLACENTAE

To the Editor:—Please give me some data or references in regard to "Concealed Internal Hemorrhage" or "Ablatio Placentae" named by Holmes.

A. S. Rose, M.D., Fayetteville, N. C.

Answer.—The following is a list of references to the subject:

Holmes, R. W.: Two Cases of Ablatio Placentae, *Am. Jour. Obst.*, 1903, xlviii, 519.
Holmes, R. W.: Ablatio Placentae, A Study Based upon Two Hundred Cases in the Literature, *Am. Jour. Obst.*, December, 1901 (complete bibliography).

FRACASTORIUS ON SYPHILIS

To the Editor:—Will you kindly publish in an early issue the English version of the famous Latin poem of the Italian physician Fracastorius, written in 1530, in which the disease syphilis is first referred to? This poem, now of great historical importance, is not available to the general practitioner, and I think that its publication would be appreciated by the other readers of The Journal as well as myself.

Paul E. Greenleaf, M.D., Bloomington, Ill.

Answer.—The celebrated poem of Hieronymus Fracastor is now about four centuries old. To its author is due the credit of having given to this disease the name which has supplanted all others and is to-day in universal use. While the poem is filled with mythological allusions it affords a good clinical description of the symptoms of the disease. It is a version in verse of a small prose treatise published by the author in 1548, entitled "De Contagionibus et Contagiosis Morbis." A translation in prose was issued by the Pilman Company, St. Louis, in 1911, for $2. It is a booklet of fifty pages. In his little essay entitled "An Alabama Student," Sir William Osler gives an account of Fracastorius with extracts from the poem. The great length of the work prevents its complete publication in The Journal.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 14. Chairman, Dr. W. H. Sanders, Montgomerv.
Alaska: Juneau, July 7. Sec., Dr. Henry C. De Vighne, Juneau.
Arizona: Phoenix, July 7-8. Sec., Dr. John Wix Thomas, Phoenix.
Colorado: Denver, July 7. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.
Connecticut: New Haven, July 14-15. Sec., Dr. Chas. A. Tuttle, New Haven. Homeopathic: New Haven, July 14. Sec., Dr. Edwin C. M. Hall, New Haven. Eclectic: New Haven, July 14. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.
Illinois: Chicago, June 23-25. Sec., Dr. C. St. Clair Drake, Springfield.
Indiana: Indianapolis, July 14-16. Sec., Dr. W. T. Gott, State House, Indianapolis.
Maine: Augusta, July 7-8. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.
Massachusetts: Boston, July 14-16. Sec., Dr. Walter P. Bowers, Room 159 State House, Boston.
Montana: Helena, June 30-July 2. Sec., Dr. Wm. C. Riddell, Helena.
New Hampshire: Concord, July 1-2. Regent, Mr. H. C. Morrison, Concord.
New Mexico: Santa Fe, July 13. Sec., Dr. W. E. Kaser, East Las Vegas.
New York: June 23-26. Chief of Examinations Division, Mr. Harlan H. Horner, Department of Education, Albany.
North Dakota: Grand Forks, July 7. Sec., Dr. G. M. Williamson, Grand Forks.
Oklahoma: Oklahoma City, July 14. Sec., Dr. John W. Duke, Guthrie.
Oregon: Portland, July 7-9. Sec., Dr. L. H. Hamilton, Medical Bldg., Portland.
Rhode Island: Providence, July 2-3. Sec., Dr. Gardner T. Swarts, State House, Providence.
South Dakota: Deadwood, July 14. Sec., Dr. Park B. Jenkins, Waubay.
Texas: Austin, June 23-25. Sec., Dr. W. L. Crosthwait, Waco.
Utah: Salt Lake City, July 6-7. Sec., G. F. Harding, 405 Templeton Bldg., Salt Lake City.
Vermont: Burlington, July 14-17. Sec., Dr. W. Scott Nay, Underhill.
Virginia: Richmond, June 23-26. Sec., Dr. J. N. Barney, Fredericksburg.
Washington: Seattle, July 7. Sec., Dr. C. N. Suttner, Baker Bldg., Walla Walla.
West Virginia: Elkins, July 1. Sec., Dr. S. L. Jepson, Wheeling.
Wisconsin: Milwaukee, June 29. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.
Wyoming: Laramie, July 9-11. Sec., Dr. H. E. McCollum, Laramie.

Special Preparation for Ophthalmologists

A statement from the University of Minnesota Medical School says that a course for the preparation of specialists in ophthalmology, covering a period of two or three years is to be offered, this course to start July 1, 1914. Opportunity will also be provided for a course in otology, laryngology and rhinology to be taken at the same time. It is planned to grant a suitable degree in ophthalmology at the expiration of the service, provided the work done is satisfactory. The plan provides for a systematic training, covering laboratory branches so far as they are related to ophthalmology, and the intention is to give the student a good foundation in these allied subjects, both laboratory and clinical, including anatomy, physiology, pharmacology, pathology, bacteriology, general medicine, surgery, experimental and clinical, neurology and other clinical branches.

It is the intention thus to broaden the foundation of the student undertaking these specialties. During this period he will have opportunity for such work as is required clinically in eye, ear, nose and throat. It is expected that this course will prepare the student more quickly and in a better manner in subjects related to ophthalmology than would be the case were the physician to enter on a long period of general practice in which he is obliged to do much work which later will be of little or no value in the practice of his specialty. There is one teaching fellowship offered of $500 for the first year, and it is expected that the amount of the fellowship will be somewhat larger for the second year of service.

Maine March Report

Dr. Frank W. Searle, secretary of the Maine Board of Registration of Medicine, reports the written examination held at Portland, March 10-11, 1914. The number of subjects examined in was 10; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 16, of whom 13 passed and 3 failed. Five candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
George Washington University	(1912)	87
Medical School of Maine	(1913)	78
Baltimore Medical College	(1913)	79
College of Physicians and Surgeons, Baltimore	(1912)	77
College of Physicians and Surgeons, Boston	(1912)	76
Harvard University	(1893) 81; (1900) 88; (1909)	93
Tufts College Medical School	(1912) 77; (1913)	80
Jefferson Medical College	(1913)	91
University of Vermont	(1913)	84
McGill University	(1901)	84

FAILED

College	Year Grad.	Per Cent.
Coll. of Phys. and Surgs., Boston	(1909) 71; (1911) 72; (1912)	63

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
University of Colorado	(1913)	Colorado
Chicago College of Medicine and Surgery	(1913)	Illinois
Tufts College Medical School	(1894)	Texas
University of Vermont	(1907) Vermont; (1912)	Vermont

California Reciprocity Report

Dr. Charles B. Pinkham, secretary of the Board of Medical Examiners of the State of California, reports that 39 candidates were licensed through reciprocity and 1 by motion of the board, Dec. 8-10, 1913. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Coll. of Phys. & Surgs., Los Angeles	(1906) Arizona; (1913)	Wisconsin
Cooper Medical College	(1906)	Oregon
Denver College of Medicine	(1902)	Penna.
University of Colorado	(1896)	Washington
Georgetown University	(1906)	Utah
Chicago Homeopathic Medical College	(1903)	Iowa
Hahnemann Med. Coll. & Hosp., Chi.	(1902) Iowa; (1905)	Illinois
Northwestern University	(1908) Illinois; (1912)	Illinois
Rush Medical College	(1909)	Illinois
University of Illinois	(1912)	Arizona
Keokuk Medical College	(1905)	Washington
University of Kansas	(1906)	Missouri
Tulane University	(1910)	Texas
College of Physicians and Surgeons, Baltimore	(1907)	Utah
Johns Hopkins University	(1901) Maryland; (1906) Maryland; (1909) Maryland; (1910) Maryland.	
Southern Homeopathic Medical College	(1904)	Maryland
Harvard University	(1902)	New York

Beaumont Hospital Medical College	(1897)	New Mexico
Missouri Medical College	(1886)	S. Dakota
Columbia University, College of Phys. and Surgs.	(1907)	New York
Cornell University	(1913)	New York
New York Homeopathic Medical College and Hosp.	(1908)	New York
Cincinnati College of Medicine and Surgery	(1880)	Arizona
Ohio Medical University	(1906)	Ohio
Western Reserve University	(1905)	Mass.
Jefferson Medical College	(1902) Penna.; (1912)	Maine
Medico-Chirurgical College of Philadelphia	(1904)	New Jersey
University of Penna.	(1900) Penna.; (1902)	Penna.
Woman's Med. Coll. of Penna.	(1891) New Jersey (1912)	Penna.

Philippine Islands Report

Dr. C. E. Norris, secretary of the Board of Medical Examiners for the Philippine Islands, reports that 33 physicians were registered during the latter half of 1913. The following colleges were represented:

College	Grad.	Examined
Chicago College of Physicians and Surgeons	(1907)	1
Rush Medical College	(1904)	1
Tulane University	(1907)	1
Grand Rapids Medical College	(1902)	1
St. Louis University	(1905)	1
Jefferson Medical College	(1892)	1
University of the Philippines, Med. Dept.	(1913)	6
University of St. Thomas, Med. Dept.	(1913)	19
University of Strassburg	(1897)	1
Medical School of Kanazawa, Japan	(1910)	1

Book Notices

A Handbook of Useful Drugs. A Selected list of Important Drugs Suggested for the Use of Teachers of Materia Medica and Therapeutics and to Serve as a Basis for the Examination in Therapeutics by State Medical Examining and Licensing Boards. Prepared under the Direction and Supervision of the Council on Pharmacy and Chemistry of the American Medical Association. Cloth. Price 50 cents. Pp. 167. Chicago. American Medical Association Press, 1914.

The object of this book, published under the auspices of the Council on Pharmacy and Chemistry, as is well expressed on its title page, is to present "a selected list of important drugs suggested for the use of teachers of materia medica and therapeutics and to serve as a basis for the examination in therapeutics of state medical and examining boards." This object seems to have been achieved. The book is a valuable practical help toward a higher standard for medical therapeutics and medical education. Recognizing the fact that a too large number of drugs is detrimental to therapeutic progress and especially a hindrance to effective medical teaching, a committee of the Council on Medical Education of the American Medical Association prepared a list of the more important drugs in general use and submitted it to the National Federation of State Medical Examining and Licensing Boards with a view to securing the cooperation of that body in largely limiting examination for license to medicaments in this list. The drugs selected by the Council on Pharmacy and Chemistry for this book were chosen from the list described. The drugs are arranged alphabetically. The information given includes a physical and chemical description of the drugs together with their pharmacology, therapeutics, dosage and practical application.

It may be pointed out that the book includes the new and the old. Official drugs whose importance warrants their inclusion have been taken from the United States Pharmacopeia, and their physical and chemical description are in accordance with the official standards; the non-official drugs have been taken from New and Nonofficial Remedies.

Following the main text are tables of solubility, the classification of drugs according to their usage, lists of drugs that may cause eruptions of the skin, discolorations of the urine and feces and drugs that are excreted in the milk. A good index completes the book.

Every student should own a copy of "Useful Drugs" to aid him in bringing scientific laboratory pharmacology to practical application, and to help him to recognize the useless drugs that are still official in the Pharmacopeia, still appear in books on practice, and constantly occur in the medical journals.

Teachers and instructors in practical therapeutics will find the book of great value in the selection of the drugs that their students must be prepared on for hospital and licensing board examinations. The book represents a much-needed advance in therapeutics by tacitly repudiating a large number of useless drugs.

Benzol as a Leucotoxin. Studies on the Degeneration and Regeneration of the Blood and Hematopoietic Organs. By Laurence Selling, M.D. Monographs of the Johns Hopkins Hospital Report, New Series, No. 2. Paper. Price, $1. Pp. 60, with 3 illustrations. Baltimore: Johns Hopkins Press, 1913.

This pamphlet gives an exhaustive review of the action of benzol (benzene, C_6H_6), on the blood-making organs, particularly the bone-marrow and on the different varieties of blood-cells. Benzol is shown to destroy the cells of the bone-marrow until the blood-making tissue becomes aplastic; but the cessation of the injections leads to regeneration in the course of two or three weeks. Examination of the cells in the process of regeneration indicates, according to the authors, the possibility of a conversion of small lymphocytes into large lymphocytes and the further differentiation of the large lymphocytes into granulocytes, erythroblasts and megacaryocytes. The conversion of erythroblasts to erythrocytes is conceived of as a physiologic process consisting in a wandering of the nucleus out of the cells.

Miscellany

The Patent Medicine Problem

An article by M. I. Wilbert (*Jour. Am. Pharm. Assn.*, 1914, iii, 572) discusses the patent-medicine problem from the pharmaceutical point of view and presents a review of some of the opinions expressed and resolutions adopted by members of the American Pharmaceutical Association during the sixty or more years of the existence of that organization.

If resolutions were as potent for good as their proposers would have them to be, the patent-medicine problem would long since have ceased to exist. Even so, however, it is pleasing to learn that pharmacists as a class have consistently opposed quackery and fraud as represented by the nostrum business and have repeatedly gone on record as favoring the degree of publicity necessary to give the purchaser a fair knowledge of the composition of the medicine he is buying. It is interesting to note, for instance, that at the second meeting of the American Pharmaceutical Association the following resolutions were adopted:

> *Resolved*, That the American Pharmaceutical Association believes that the use and sale of secret or quack medicines is wrong in principle and is, in practice, attended with injurious effects to both the profession and the public at large, and believes it to be the duty of every conscientious druggist to discourage their use.
>
> *Resolved*, That this association earnestly recommend to our pharmaceutical brothers to discourage by every honorable means the use of these nostrums; to refrain from recommending them to their customers; not to use any means of bringing them into public notice; not to manufacture or to have manufactured any medicine the composition of which is not made public, and to use every opportunity of exposing the evils attending their use and the false means which are employed to induce their consumption (*Proc. Am. Pharm. Assn.*, 1853, p. 17).

Three decades later (*Proc. Am. Pharm. Assn.*, 1885, xxxiii, 394), after a somewhat comprehensive study of the problems involved in the sale of patent medicines by retail druggists, a special committee presented a report including the following expression of opinion:

> "All medicines, and articles used as such, concern the health of those who use them and put dependence on them. By action or failure of action, a medicine is liable to prove hurtful when misapplied. Therefore, it is the right of a purchaser of medicine to receive information of its constituents, their names and proportional quantities. And it is a legitimate act of the state—so far as it deems expedient—to see to it that such information, in printed form, is placed on each package of articles of medicines, as a condition of their legal sale.
>
> "Moreover, legislation requiring the composition of medicines to be given to the consumer is entirely in accord with the spirit of the institutions of the United States, because it is legislation tending to make the individual responsible for taking care of himself and tending to secure him in the means of self-preservation. The purchaser of a medicine is provided with a record of its constituents, given in terms defined by published standards: now he may guide himself, in his own discretion, or with professional aid, by the information given in the record of constituents, or he may neglect to so guide himself, and depend on advice given on the wrapper of the medicine, in the exercise of his personal responsibility. The state has done its duty, and given the individual the opportunity for the exercise of discretion. The opportunity has an educational value to the individual."

Thirty years later, at the meeting of the American Pharmaceutical Association in Nashville in 1913, that association appointed a committee to inquire into and report on the problems involved in the patent-medicine business. The "Commission on Proprietary Remedies," as it is called, is to consider the following general propositions:

> "1. To inquire into and report to the Council, from time to time, on the general subject of proprietary medicines, in their relation to pharmacy, medicine and the public health.
>
> "2. To inquire whether any of the proprietary medicines, commonly known as patent medicines, contain alcohol or narcotic drugs in sufficient amount to render them liable to create a drug habit, or to satisfy such habits where otherwise created.
>
> "3. To inquire whether, or to what extent, the commonly advertised patent medicines contain potent drugs in sufficient amount to render them dangerous in the hands of the laity.
>
> "4. To inquire into the extent to which patent medicines are fraudulently advertised, or differ in properties or origin from the claims made for them, and the extent to which they are advertised for the cure of diseases generally recognized by the medical science as at present being incurable" (*Jour. Am. Pharm. Assn.*, 1913, ii, 1195).

If, as is to be expected, the present committee pursues its investigation along the lines mapped out by the earlier leaders in American pharmacy, and if it will fearlessly report its findings, the American public and the American medical profession will have secured an efficient ally in the present-day fight to eliminate quackery and fraud in the treatment of diseases.

In the summary of the recent accomplishments attempting to solve the patent-medicine problem, Wilbert expresses the opinion that "the questions involved are not to be considered as being answered until they are answered correctly, and that from the point of view of the public the influence of patent medicines on the health and welfare of the individual is the only factor deserving of consideration. Bearing this latter fact in mind, it would appear desirable that all branches of the drug trade give the patent-medicine problem renewed and serious consideration and make an honest effort to adjust their interests in accord with the interests of the public, and thus effectually counteract the frequently made assertions that the economic questions involved must outweigh all others so far as the drug trade may be concerned."

Drunkenness in Massachusetts

The legislature of Massachusetts in 1913 provided, by resolution, for a commission of five persons to investigate drunkenness in that state. The report of the commission is printed in a pamphlet as House Document 2053. It gives the number of arrests for drunkenness in the state during the previous year, the result of hospital treatment in the state institutions for treating inebriates, and discusses the means and measures for the curtailing of the liquor-habit and the prevention of drunkenness. The commission believes that the state of Massachusetts is not yet ready for state prohibition, but that local option is a good measure. As substitutes for saloons it is thought that meeting-places for men should be provided and that possibly for this purpose greater use could be made of the public-school buildings. Recommendations are made for additional legislation to regulate and control the liquor traffic and, as far as possible, prevent drunkenness, which seems to be on the increase in the state. The report is the logical result of a practical, sensible consideration of the liquor problem.

How to Judge a Doctor

Recently there appeared in the department "How to Keep Well" of the Chicago *Tribune* the following query and a reply, which we believe deserves reprintiing as a guide to the physician himself. The correspondent wrote:

> "Some time ago I saw an article in your columns saying that as long as people would patronize an incompetent physician, simply because of his genial manner, they would have themselves to thank for their misfortunes. As far as I can see, the ordinary layman is in no position to judge a physician, and no one in a position to judge will commit himself further than to say that so-and-so is a recognized specialist in his line. How is the layman to judge a general practitioner?"

And the answer was:

> "By the judgment and sense he shows in the ordinary affairs of life; by his attendance at hospitals, clinics, medical society meetings; by his standing with other physicians; by the books and journals he reads; by his knowledge of medicine, medical judgment and skill. Some of these items are get-at-able in every case, and all of them in some cases. At the present time the opportunities for popular education on medical subjects are so abundant that the ordinary layman should be able to judge fairly well between the physician who knows his business and the bluffing ignoramus."

Medicolegal

Proof Rendering Roentgenogram Admissible in Evidence

(Prescott & Northwestern Railroad Co. vs. Franks (Ark.), 163 S. W. R. 180)

The Supreme Court of Arkansas says that it is now a well-recognized fact that by the aid of proper apparatus a picture of the bones of the human body may be obtained that will more or less define the skeleton and show any injuries that may have resulted to the bones, or any foreign substance that may be lodged in the body. Therefore roentgenograms are admissible in evidence when proper proof of their accuracy and correctness is produced. In this case the plaintiff (Franks) had suffered a dislocation and fracture of his hip. His attending physician admitted that he had never had any experience in taking roentgenograms but testified that he was present when the photograph in question was taken; that a glass plate was placed under the injured member of the plaintiff, and the Roentgen ray placed over him, and by reflection of the light from the roentgenoscope the negative was made; that he saw it before it was delivered to the photographer to be developed; that the roentgenogram exhibited to the jury was the same as the impression on the glass which he saw just after it was taken. The witness, although he was not a graduate of any medical school, was a practicing physician and surgeon, and had been for fifteen years. His testimony, detailed above, showed that he was present when the picture was taken, and was familiar with the anatomy of the human body. Therefore the court thinks there was sufficient proof of the accuracy and correctness of the photograph, and that there was no error in admitting it in evidence.

Liability of Operating Surgeons for Negligence of Others—Admissibility of Evidence

(Hunner vs. Stevenson et al. (Md.), 89 Atl. R. 418)

The Court of Appeals of Maryland reverses, on the defendant's appeal, a judgment for $1,000 rendered against him, granting him a new trial. The court says that, June 20, the defendant performed an operation on a Mrs. Stevenson which consisted in the removal of the lower third of the right kidney and drainage of an abscess around the kidney lying between the kidney and the bowel. About five weeks afterward Mrs. Stevenson returned to her home, and, September 9, a piece of gauze which had been left in her was removed by her family physician. A week after that some rubberized silk was taken out by Mr. Stevenson, her husband. A "cigarette drain" had been used, which was covered with rubberized silk.

The court reached the conclusion that the appellant (defendant) could not be held responsible for the negligence, if any, of the hospital physicians, nurses, or interns in the dressing of the wound after the operation was performed, if he did not know of, or was not privy to, such negligence, and it was not discoverable by him in the exercise of ordinary care. At this day, when it is well known that there are physicians and surgeons of special skill in particular branches of their profession, it could not safely be announced as a general rule of law, applicable to such cases as this, that a surgeon who performs an operation is liable for the negligence of other physicians, nurses, or interns in hospitals in the after-treatment, unless he specially undertakes such employment. A surgeon may be called many miles from his residence to perform an operation, and, if he is to be held responsible for the negligence of others after the operation, it might mean either that one of special skill would refuse to perform such operations at distant points, or that his charges would be such that no one of moderate means could employ him. It might be detrimental to the public if such a surgeon were required to attend to the after-treatment, as it would be impossible for him to do so and perform many operations. It would be unreasonable to expect one performing operations in half a dozen different hospitals to continue to dress the wounds and have personal charge of the after-treatment in all cases until the patient is discharged from the hospital.

As reflecting on the defendant's right to leave the dressing of the wound to nurses and other attendants in the hospital, the question was relevant whether the postoperative dressing of wounds, as he had described in Mrs. Stevenson's case, was difficult. It was also proper to ask a medical witness what the practice was among reasonably diligent, competent, and skilful surgeons practicing in hospitals with reference to the personal care, after-care, and treatment of the wounds of patients on whom they had operated. As the plaintiffs asserted that pulmonary tuberculosis resulted from the gauze and rubberized silk being left in the wound, it was proper to ask another medical witness to state how, in his judgment, the sinus left from this wound became infected with tuberculosis, and what connection, if any, the tuberculous condition of the sinus had with the operation or subsequent treatment of the case by the defendant. It was proper, too, to let the jury know how long it usually takes such a wound as described in the testimony to heal. The fundamental error in this case was as to the responsibility of a surgeon operating under such conditions as the defendant did.

Presence of Tuberculous Person May be Considered in Awarding Custody of Children

(Kirkland vs. Matthews (Tex.), 162 S. W. R. 375)

The Court of Civil Appeals of Texas reverses a judgment awarding the custody and care of certain minor children, whose mother was dead, to their father, rather than to their aunt, in which one of the points raised was that living in the father's family was his second wife's mother, who was afflicted with tuberculosis. The court says that the aunt offered to prove that a member of the father's family was afflicted with tuberculosis, a contagious and dangerous disease, but this proof was rejected on the father's objection. The purpose in offering proof of this fact was to show that the minors, should they be awarded to their father, would come into close association with one suffering from a dangerous and contagious malady, and that this was a circumstance to be considered in determining whether the best interest of the minors would be subserved by placing their custody with their father. The court thinks that the testimony was admissible on the issue suggested, and that the trial court erred in rejecting it. What is for the best interest of the children is the question of prime importance in cases of this kind, and any evidence showing or tending to show that their welfare would not be best subserved by placing them in the custody of a contending party should be admitted and considered.

Unlawful Practice of Medicine

(Allen vs. State (Okla.), 138 Pac. R. 178)

The Court of Criminal Appeals of Oklahoma says that it is a penal offense under the laws of Oklahoma for any person to practice medicine or surgery in Oklahoma without having at the time a valid unrevoked certificate. An information charging a person with the violation of that provision of the code which penalizes persons for prescribing or administering any drug or medicine now or hereafter included in materia medica in the treatment of disease, injury, or deformity of human beings, must be substantiated by proof of the fact that some such drug or medicine was so prescribed or administered. This prosecution was begun prior to the adoption of the revised laws, for a violation of this provision. A careful reading of the record disclosed that the accused had been administering certain medicines, but no witness named any drug or medicine prescribed or administered by him, nor was there any proof in the record disclosing that any drug or medicine was administered which was included in materia medica, as required. Without doubt the jury should have been instructed, as requested, that the state had failed to introduce evidence sufficient to establish the guilt of the defendant as charged in the information, and they should return a verdict of not guilty.

Thirty-Ninth Annual Meeting held at Boston, May 1921, 1914

The President, Dr. J. Whitridge Williams, Baltimore, in the Chair

A list of the newly elected officers was published in The Journal, June 6, p. 1820.

Forward Fixation of Cervix as Predisposing Cause of Some Retrodeviations of Uterus

Dr. Edward Reynolds, Boston: The supports of the uterus are largely muscular, with the exception of the forward attachments of the cervix. The shortness of the latter forms an essential element in the anteflexion of the cervix. Firm, forward fixation of the cervix, while the fundus is comparatively movable, creates a predisposition to retrodeviations. The release of the forward fixation of the cervix as a preliminary to the performance of the standard operations for the retrodeviations adds greatly to their percentage of success.

DISCUSSION

Dr. Herman J. Boldt, New York: Heretofore I have always looked on the shortened, and not infrequently indurated, condition of the sacro-uterine ligaments as being the main factor in causing retroversion of the cervix, and have on a number of occasions cut the shortened ligaments to overcome the backache of which many of these patients complain, several times relieving this symptom. That the holding forward of the fundus is due to the action of the round ligaments is questionable in the greater number of such instances. These ligaments are not taut, except when the bladder and rectum are full. The condition is usually an association of anteflexion of the body of the uterus with a retroversion of the cervix; and unless there be an atrophy of the anterior cervicocorporal junction, the tissue at this junction is unyielding — indurated — and it is impossible to straighten it permanently by manual or mechanical means. Hence the mechanical dysmenorrhea of which many patients frequently complain. The usually present shortened anterior vaginal wall is part of the congenital malformation, and is an additional factor in causing the retroversion of the cervix. I have always regarded the shortened and thickened sacro-uterine ligaments to be a low-grade inflammatory process — a parametritis posterior. Furthermore, when the condition is of long standing and more or less atrophy has taken place in the anterior part of the cervix at the flexion angle, because of long duration and not infrequently increased size of the body of the uterus, the organ cannot straighten itself by any physiologic factor brought to bear on it. We may see the uterus assume a position farther backward in the pelvis, thus constituting a retroposition; and then the intra-abdominal pressure may cause a still more acute flexion angle.

Dr. Henry T. Byford, Chicago: I have in many cases separated the bladder from the uterus through a transverse incision and have drawn the parts together from the side to the median line, with the idea that I was getting support in front of the cervix which would hold it back more.

Dr. I. S. Stone, Washington, D. C.: The Mackenrodt fixation operation for retroversion will answer the same purpose and overcome permanently the retroversion.

Dr. J. Wesley Bovée, Washington D. C.: In certain anomalies of development there is an abnormally high attachment of the uterosacral ligaments to the cervix and an abnormally low attachment of the anterior wall of the vagina. These defects may be remedied by severing the anterior wall from the cervix, attaching it at a higher point and severing the uterosacral ligament from the cervix and attaching it to the lower point, thus giving stronger posterior leverage on the posterior wall of the uterus.

Dr. James R. Goodall, Montreal: The type of acute anteflexion of the uterus and the type of retroflexion are two distinct types which cannot be considered as belonging to one class. For instance, if we take young girls who complain of severe dysmenorrhea, we find associated conditions of the vagina and pelvis. Associated with an acute anteflexion of the uterus there is a short anterior lip of the cervix and a long posterior lip. That type of uterus when removed from the body and held by the cervix cannot be undone. The anterior uterine wall is very fibrous in part and it is a type of uterus which seldom, if ever, becomes retroverted or retroflexed. In the other type of case, in which retroversion and retroflexion take place, there is a lack of tone and a tendency to enteroptosis even before pregnancy has taken place, and with that type of uterus the fundus can be flopped about in very few hours after death.

Dr. Edward Reynolds: There is a distinction between these two classes of retroverted and anteflexed uteri. Retroversion seldom occurs in the class in which the anterior wall at the angle of flexion is hard and firm. When we think that the cervix is the cause of the mechanical dysmenorrhea, release of the anterior fixation and posterior discission will straighten the uterus.

An Internal Alexander Operation

This paper, by Dr. Henry T. Byford, Chicago, will appear in full in The Journal.

Effect of Laparotomy on the Circulation

Dr. W. D. Gatch, Indianapolis: In a series of experiments carried out on dogs, I took simultaneous tracings of the intrathoracic pressure of the intra-abdominal pressure, of the pressure in the inferior vena cava, and of the general blood-pressure. I raised the intra-abdominal pressure by injecting warm salt solution into the peritoneal cavity. The tracings showed that the intra-abdominal pressure and the pressure in the inferior vena cava were always equal and rose and fell together. When the intra-abdominal pressure is elevated until it is higher than the blood-pressure, the circulation through the abdomen is abolished, the abdominal viscera being found bloodless at necropsy. The chief and essential cause which propels the blood through the abdominal organs is the beat of the heart. The well-known fact that pressure on the abdomen increases the output from the inferior vena cava is not evidence against this view, because such increase is not maintained unless the circulation is greatly depressed. The absence of valves in the abdominal veins prevents any variations in intra-abdominal pressure due to movements of the abdominal walls from pumping the blood toward the thorax with any degree of efficiency, because as soon as the pressure is released there is a regurgitation. That the heart alone is capable of keeping up the abdominal circulation is proved by experiments.

The effect of anesthesia so deep as to abolish completely the tone of the abdominal wall is to promote the accumulation of blood in the abdomen and limbs, and not uncommonly causes a failure of the circulation during and after operation. It is fortunate that laparotomy is nearly always performed with the patient either in the horizontal or in the Trendelenburg position, for if it were usually done with the patient deeply anesthetized and in the feet-down posture, many more fatalities would occur. Operations both on animals and on man are much better borne under an anesthesia so light as to preserve the tone of the muscles. This is the reason why there is much less so-called shock under nitrous oxid-oxygen anesthesia than under anesthesia due to more powerful agents.

Treatment of Procidentia of Uterus by Interposition Operation

Dr. Thomas J. Watkins, Chicago: Vesico-uterine transposition should be made before much protrusion through the vaginal orifice results, as the prolapse rapidly increases after this has taken place; the more the prolapse, the greater the dangers of recurrences following the operation. Vesicouterine transposition cures cystocele, the most important pathologic feature. An occasional recurrence of the uterine prolapse will occur, except in cases in which the vaginal canal can be practically obliterated. This recurrence, however, is not serious, as it can be easily remedied. The operative technic should be adapted to each individual case.

End-Results of Interposition of the Uterus

Dr. John Osborn Polak, Brooklyn: Interposition operations should be limited to women at or past the menopause, with a relatively small uterus, and when the procedure is elected in those still menstruating, sterilization by tubal ligation should be done at the time of operation. The cases of prolapse in which sliding takes place in the postpubic cleavage plane are not corrected by this procedure. The morbidity is wholly due to technical defects, namely, improper preparation and imperfect hemostasis, vesical injury, etc. In anteverting the uterus the anterior wall of the uterus should rest on the fascial plate just behind the pubis; the fundus should not be brought under the arch, as excessive anterior displacement not only favors recurrence, but anteflexes the uterus and interferes with drainage. The curettings from uteri about to be transposed should always be examined, as degeneration may occur, and hysterectomy is easy after this operation.

AMERICAN DERMATOLOGICAL ASSOCIATION

Thirty-Eighth Annual Meeting, held in Chicago, May 14-16, 1914

(Concluded from page 1921)

External Vaccine Therapy

Dr. Harvey P. Towle, Boston: The results of the tentative experiments with external vaccine therapy were so encouraging in the Massachusetts General Hospital in 1912 that the method has been used with constantly increasing frequency. The present paper is based on the personal observation of more than a hundred and fifty private patients in whom vaccine was used externally. The indications are that external vaccine therapy is most efficient in the treatment of the acute inflammation of infectious disease whose seat is superficial and therefore easily reached from without. Of all infectious processes the staphylococcic is the most easily influenced by external vaccine therapy, and in this the resemblance to the internal method is exact. Vaccine injections are never more efficient than in the treatment of furunculosis, but have also been used successfully in cases of acne, sycosis, and with seeming success in psoriasis and also in oily seborrhea of the scalp. The results on the superficially seated lesions of impetigo contagiosa were usually excellent. Tuberculin was also used externally in several cases of lupus vulgaris, with good effect.

DISCUSSION

Dr. Joseph Grindon, St. Louis: About three weeks ago I was called to see a case of lupus which had existed for twenty-five years. Various treatments had failed to give more than fair temporary improvement. I thought that perhaps an additional rubbing in of the organism might produce a large output of the antibodies. So I took the Moro ointment, undiluted, and twice a week rubbed it in for five minutes at a time. There was quite a decided improvement, which continued for several weeks. After a month, however, the lesions flared up again, and I then lost track of the patient.

Dr. Joseph Zeisler, Chicago: Many cases of impetigo contagiosa have cleared up under my observation with simple treatment in five days. I remember a case of lupus erythematosus in which I performed scarification and applied a little phenol (carbolic acid), and in a week the patient was cured. There are so many different factors entering into the cure of our cases that it is very difficult to draw any conclusions at all. The mechanical element of rubbing grease into a scaly eruption might help some. I admire Dr. Towle's enthusiasm, and do not wish to criticize him.

A Case of Generalized Congenital Keratodermia

Dr. Frederick S. Burns, Boston: The patient whose case I shall report was 16 years of age. The dermatosis was generalized, showing special preference for the flexures of the hands, knees and feet, and the face. The type of lesion was that of an abnormal cornification varying from spine-like elements to marked keratotic thickening. Exfoliation was slight. The process extended on the lips, buccal and nasal mucous membrane, presenting on these surfaces a rather dry superficial thickening that closely resembled leukoplakia. The corneas were thickened and uneven, and surrounded by enlarged blood-vessels which also infiltrated the cornea. The intrinsic tissues of the eyes were unaffected. Deafness was total. The Wassermann was negative. The mucous membrane lesions were unusual, and those of the eyes and ears extremely rare.

DISCUSSION

Dr. Joseph Grindon, St. Louis: I am glad that Dr. Burns has once more called attention to the distinction between hyperkeratosis congenita and ichthyosis. So far as I am acquainted with the conditions, there is no such thing as congenital ichthyosis; that is, it is never present at birth, although developing in the first and second years of life.

Dr. D. W. Montgomery, San Francisco: I should like to ask Dr. Burns if the usual clinical picture does not show that the palms of the hands are old and smooth.

Dr. S. Pollitzer, New York: Please differentiate this process from the possibility of an atypical acanthosis.

Dr. A. Ravogli, Cincinnati: It is difficult for me to understand the difference in these cases between pityriasis rubra pilaris and ichthyosis. In ichthyosis we have the affection on the surface of the epidermis, but the effect does not go inside into the follicles. In this case, according to the pictures passed around, the openings of the hair follicles are all studded with epidermis, and I have always found this condition in pityriasis rubra pilaris. In ichthyosis the palms, soles and nails are very seldom affected in the way described in this case, which suggested pityriasis rubra pilaris.

Dr. Frederick S. Burns, Boston: In answer to Dr. Montgomery's question as to the involvement of the palms and soles, the process, as seen at the time when the photographs were taken, does not show the aggravated condition present a year ago. At that time it presented the appearance of pityriasis rubra pilaris or keratosis follicularis. It has been my impression from reading text-books and various papers, and looking over the literature, that there has seemed to be a consensus of opinion, although an artificial one, that the palms, soles, face and scalp are not usually affected in ichthyosis vulgaris. I do not emphasize that point, because I realize that it is a clinical and artificial distinction. The existence of a greater degree of inflammatory infiltration in the papillary layer of the skin in cases of ichthyosis vulgaris, however, is very common. In my case such changes were entirely absent; but there was a slight hypervascularity, which may help to explain the underlying erythema, and that may be a part of the acanthosis hyperkeratosis having to do with the deformity of the skin.

Regarding Dr. Pollitzer's question with reference to acanthosis, the clinical symptoms presented no pigmentation.

I wish to lay special emphasis on the unusual involvement of the mucous membranes and the organs of special sense, because there seemed little doubt, after consultation with the various specialists who concerned themselves with the examination of the eyes and ears, that the condition of the skin was contiguous with any part of the process having to do with the dermatosis.

Report of a Case of Colloid Degeneration of the Skin

Dr. Milton B. Hartzell, Philadelphia: From a study of one typical case occurring in a man, aged 43, I am convinced that colloid degeneration of the skin of the type represented by the so-called colloid milium is not a disease of the elastic tissue alone, but affects the collagen and elastin in equal degree. The cells of the epidermis may share in the degeneration, although this is probably infrequent.

DISCUSSION

DR. G. F. FOX, New York: I was convinced that the cases which I reported many years ago as colloid milium were not true cases of colloid degeneration, but similar to a number of cases that had been described. In my cases the tumors looked firm, but were soft, and when dug out of the skin were found to be cystic and removal was followed by an extreme amount of hemorrhage. There was scarcely any cicatrix left after healing.

DR. CHARLES J. WHITE, Boston: The case which I reported some years ago was very different clinically, in that it had very few lesions and decidedly larger ones. Histologically, Dr. Hartzell's patient and my own are extraordinarily similar. My case, however, was much farther advanced than Dr. Hartzell's.

DR. MILTON B. HARTZELL, Philadelphia: It seems to me it is folly to give different names to this one condition. Why not call it degenerative elastin?

Urticaria Pigmentosa, Particularly in Regard to Its Pathology

DR. FRANK CROZER KNOWLES, Philadelphia: I have seen five cases of this disease. It should be dissociated from urticaria, as the course, symptoms and the histologic mast-cell picture are entirely distinctive. A congenital abnormality of the skin has apparently been proved in urticaria pigmentosa by finding abundant mast-cells in the clinically normal skin of these patients. A congenitally abnormal skin is more easily acted on. Some toxin apparently is the cause of this affection, and it probably does not act on normal skin. Its nature and mode of action are unknown.

Personal Observations on Two Thousand Cases of Skin-Disease in the Negro

DR. HENRY H. HAZEN, Washington, D. C.: The skin-diseases more prevalent among negroes than white persons are dermatitis papillaris capilliti, keloids, dry seborrhea, syphilis, tinea tonsurans, urticaria and vitilligo. Alopecia areata, cancer, eczema, erythema, furuncles and boils, angiomas and nevi, *Pediculus capitis* and psoriasis are less prevalent among negroes than among white persons.

Diffuse Erythematous Lupus Treated with Tuberculin

DR. AUGUST RAVOGLI, Cincinnati: My patient, a woman, aged 24, exhibited a typical clinical picture of this disease, with a positive Moro and a negative Wassermann. Local treatment proving ineffective, I resorted to the use of tuberculin T. R., injecting 0.01 mg. into the back. The following day the patient's fever was 104 F., pulse 108, respirations 34. Her face was red and edematous, the eyes closed. In many places an eruption of blisters had formed, leaving extended excoriations discharging serum. Fever continued, ranging from 101 to 105 F., with low delirium, and less than two weeks after the injection the patient died. The clinical diagnosis was acute miliary tuberculosis. A necropsy was refused. I believe that for diagnostic purposes, used locally, tuberculin is safe, but for injection it is dangerous. I am sure that in my case it aroused into acuity a dormant tuberculosis, the patient dying from a tuberculous septicemia. Tuberculin for treatment, even in the smallest dose, is a dangerous remedy.

DISCUSSION

DR. W. A. PUSEY, Chicago: The process which caused the patient's death can only be surmised, but it seems to me we can reasonably conclude that the patient was in a condition of excessive hypersensitiveness to tuberculous toxins. She showed an excessive reaction, giving evidence of acute poisoning within twenty-four hours after the injection. That would exclude the reaction from contaminating infection. The point ought to be made that in a given patient, in a condition of hypersensitiveness, an incredibly small amount of anaphylactic substance produces reaction, and that we are open to these anaphylactic reactions in spite of the most excessive precaution and the greatest skill.

DR. D. W. MONTGOMERY, San Francisco: It occurred to me that this patient might have been tuberculous, and that this process was causing the lupus erythematosus. Therefore, the tuberculin might have excited this toxin into greater activity, and thus caused death. That would be one explanation.

DR. S. POLLITZER, New York: I think it would be a misfortune if, on the basis of this experience and a few others reported, we were to give up so valuable a remedy as tuberculin injections. The present tendency in the use of tuberculin is to give much smaller doses than 0.01 mg. as an initial dose, and if 0.001 or 0.0001 mg. is given, accidents will possibly be avoided. So far nothing has happened from the use of 0.0001 mg. of tuberculin. If the patient bears that well, further injections can be given.

AMERICAN PEDIATRIC SOCIETY

Twenty-Sixth Annual Meeting held in Stockbridge, Mass., May 26-28, 1914

The President, DR. SAMUEL M. C. HAMILL of Philadelphia, in the Chair

A list of the newly elected officers was published in THE JOURNAL, June 6, p. 1820.

Diagnosis of Whooping Cough by the Complement-Deviation Test

DR. ALFRED FRIEDLANDER, Cincinnati: [An account of this work was published in THE JOURNAL, March 28, 1914.]

DISCUSSION

DR. ROWLAND G. FREEMAN, New York: While this work seems promising, there is a general impression that we are still uncertain as to whether we have really found the specific organism of whooping cough. In one laboratory in New York they have been experimenting all winter but with no results.

DR. CHARLES GILMORE KERLEY, New York: Dr. Freeman of London has used the vaccine on 1,134 cases of whooping cough, in doses of two million twice a week. Used in conjunction with the pneumococcus vaccines he felt that the results were good.

DR. SAMUEL S. ADAMS, Washington, D. C.: It seems that the value of this test hinges on the question of its making an early diagnosis of whooping-cough possible. It seems to me that if this test is to be of value we must get the child before there is a distinct history suggestive of whooping-cough.

DR. L. EMMETT HOLT, New York: The close resemblance between influenza and whooping-cough in some instances makes it very desirable to differentiate them bacteriologically. During the past winter we had an epidemic of influenza in the Babies Hospital and took cultures from all the inmates of the institution, and found the influenza organism in a large proportion of the cultures. This close resemblance between whooping-cough and influenza may account for negative results with the test.

Endocarditis in Children

DR. FLOYD M. CRANDALL, New York: It is undoubtedly true that a certain amount of degeneration of the heart muscle occurs during the course of every acute febrile disease or intoxication. It is difficult to believe that in some of the less severe types which run a favorable course any marked degree of myocarditis or pericarditis is present. The probability of grave myocarditis, however, must never be forgotten. Examinations for its detection must be frequent and careful, for on it more than on any other element depends the prognosis and much of the treatment. I have come to rely on four symptoms as particularly suggestive of muscular involvement. The earliest to appear is irregular heart action, and usually this is the most distinctive symptom. Syncope is characteristic of decided myocarditis, particularly in diphtheria. In addition to these two symptoms cyanosis and this has taken place; the more the prolapse, the greater the dangers of recurrences following the operation. Vesicouterine transposition cures cystocele, the most important pathologic feature. An occasional recurrence of the uterine prolapse will occur, except in cases in which the vaginal canal can be practically obliterated. This recurrence, however, is not serious, as it can be easily remedied. The operative technic should be adapted to each individual case.

End-Results of Interposition of the Uterus

Dr. John Osborn Polak, Brooklyn: Interposition operations should be limited to women at or past the menopause, with a relatively small uterus, and when the procedure is elected in those still menstruating, sterilization by tubal ligation should be done at the time of operation. The cases of prolapse in which sliding takes place in the postpubic cleavage plane are not corrected by this procedure. The morbidity is wholly due to technical defects, namely, improper preparation and imperfect hemostasis, vesical injury, etc. In anteverting the uterus the anterior wall of the uterus should rest on the fascial plate just behind the pubis; the fundus should not be brought under the arch, as excessive anterior displacement not only favors recurrence, but anteflexes the uterus and interferes with drainage. The curettings from uteri about to be transposed should always be examined, as degeneration may occur, and hysterectomy is easy after this operation.

The President, DR. SAMUEL M. C. HAMILL of Philadelphia, in the Chair

A list of the newly elected officers was published in THE JOURNAL, June 6, p. 1820.

Diagnosis of Whooping Cough by the Complement-Deviation Test

DR. ALFRED FRIEDLANDER, Cincinnati: [An account of this work was published in THE JOURNAL, March 28, 1914.]

DISCUSSION

DR. ROWLAND G. FREEMAN, New York: While this work seems promising, there is a general impression that we are still uncertain as to whether we have really found the specific organism of whooping cough. In one laboratory in New York they have been experimenting all winter but with no results.

DR. CHARLES GILMORE KERLEY, New York: Dr. Freeman of London has used the vaccine on 1,134 cases of whooping cough, in doses of two million twice a week. Used in conjunction with the pneumococcus vaccines he felt that the results were good.

DR. SAMUEL S. ADAMS, Washington, D. C.: It seems that the value of this test hinges on the question of its making an early diagnosis of whooping-cough possible. It seems to me that if this test is to be of value we must get the child before there is a distinct history suggestive of whooping-cough.

DR. L. EMMETT HOLT, New York: The close resemblance between influenza and whooping-cough in some instances makes it very desirable to differentiate them bacteriologically. During the past winter we had an epidemic of influenza in the Babies Hospital and took cultures from all the inmates of the institution, and found the influenza organism in a large proportion of the cultures. This close resemblance between whooping-cough and influenza may account for negative results with the test.

Endocarditis in Children

DR. FLOYD M. CRANDALL, New York: It is undoubtedly true that a certain amount of degeneration of the heart muscle occurs during the course of every acute febrile disease or intoxication. It is difficult to believe that in some of the less severe types which run a favorable course any marked degree of myocarditis or pericarditis is present. The probability of grave myocarditis, however, must never be forgotten. Examinations for its detection must be frequent and careful, for on it more than on any other element depends the prognosis and much of the treatment. I have come to rely on four symptoms as particularly suggestive of muscular involvement. The earliest to appear is irregular heart action, and usually this is the most distinctive symptom. Syncope is characteristic of decided myocarditis, particularly in diphtheria. In addition to these two symptoms cyanosis and precordial distress are very suggestive of muscle involvement. In the later stages the occurrence of cyanosis and edema is of graver significance in children than in adults. It is usually impossible to determine the condition of the heart muscle in a young child unless examination is made during sleep as well as during waking hours. If anemia is found to be marked the prognosis may not be so gloomy, as its relief may mitigate the symptoms. A point of great interest is the occasional rapidity of the development of the physical signs of endocarditis. I have heard a loud endocardial murmur develop in a closely watched child in eighteen hours. Other things being equal, I find it difficult to believe that a loud rasping murmur is not more serious than a soft blowing one. The physician who ignores the gravity of a cardiac murmur and lightly says that the child will grow out of it is taking almost a criminal risk. It is true that some children do change for the better, but the unfortunate opposite has in my experience been the more frequent result. The earlier the primary endocarditis occurs the better is the ultimate prognosis. An aortic lesion is very dangerous in a child, but aortic insufficiency is unfortunately rare in children. Anemia is a contributing factor to weakness and fatty degeneration of the heart muscle. The sources of infection of acute rheumatism are still somewhat uncertain, but the reasons for the removal of the tonsils in a rheumatic child are vastly greater than in any other constitutional type. In the treatment of endocarditis the management of the acute stage has been a comparatively simple matter, resolving itself into rest in bed for at least six weeks or two months. If the heart becomes irregular or too rapid, I insist on continuing the quiet. After the child is out of bed with a murmur many difficult problems present themselves. I am more and more convinced that to maintain the restrictive treatment too long after the preliminary stage is a mistake and may defeat its own object. In regard to the exercise which may be permitted, the action of the heart under exercise is the most reliable guide. In the management of this condition arbitrary rules do harm rather than good. In few other conditions is it more essential that we study the case and treat the patient rather than the disease.

DISCUSSION

Dr. Henry Dwight Chapin, New York: One feature in connection with these cases is the tendency to acute dilatation under great stress. In young athletes permanent damage is sometimes done. The athletics in our schools are under the charge of a director who is frequently not sufficiently informed in regard to the dangers of undue stress, and the advice of the physician is not sought in regard to matters relating to athletics.

Dr. Henry I. Bowditch, Boston: The child with a damaged heart does not have a fair show in life. On close observation it may be seen that family history plays a part in these cases. There are often other cases of endocarditis in the same family, and it is also interesting to note the association with streptococcic infection of the tonsils.

Dr. Fritz B. Talbot, Boston: If we study the family history of these cases it will be found more often that there are or have been other cases in the same family. The history of a case of endocarditis which I have just seen shows that the sister had rheumatism and endocarditis three weeks before. It seems to me that rest in bed for six weeks or two months is rather too short a time for most cases.

Dr. J. P. Crozer Griffith, Philadelphia: It is possible that where there is a certain degree of debility the patient may be kept in bed longer than he should be. These patients may be divided into three classes: (1) A small class where there is absolute failure of compensation; (2) a larger class which responds well to treatment and in which recovery usually follows; (3) a class in which there is a tendency to anemia not yielding readily to treatment. There are heart cases which in spite of arsenic, etc., still remain discouraging.

Dr. A. D. Blackader, Montreal, Canada: In regard to the effect of rheumatic endocarditis on development, it has been pointed out that growth is dependent on wide arteries and low blood-pressure. A slight endocarditis, by lowering the blood-pressure, favors wider arteries and an increase in growth, and these children may be found to be a little taller than others in the same family. Another point is the advantage of giving small doses of potassium iodid in these cases of endocarditis in children. This drug may be given in small doses for three, four or five weeks after the temperature has become normal. Its effects on acidosis are well known and it is believed to have some effect on the viscosity of the blood. The after-treatment of cases in which endocarditis has developed is a matter of judgment. Children with mild lesions confined to the mitral valve, excepting for the more strenuous exercises, should be permitted to develop the heart during the period of general development.

Dr. I. A. Abt, Chicago: Aortic lesions in children are not as rare as has been supposed. I have seen an increasing number of cases. In these children with murmurs, where there is a slight temporary dilatation after exercise, what should one do? It is very difficult to keep a boy in this condition in bed. No absolute rule can be laid down. It is a question of the individual case.

Dr. Rowland G. Freeman, New York: No one has spoken of the value of the Roentgen ray in these cases of endocarditis. When a child shows an improvement in symptoms he should be subjected to roentgenoscopy. In one case coming under my observation the child seemed to be gaining, and showing an improvement, it was allowed to get up. Roentgenoscopy showed the condition to be worse than when the first picture was taken. In the management of these cases one should be controlled more by the Roentgen ray than by the clinical examination.

Dr. D. J. Milton Miller, Atlantic City, N. J.: There are a small number of cases of adventitious murmurs not due to endocarditis, but which are exceedingly difficult to diagnose. These cases are sometimes let go without treatment and sometimes disastrously. In endocarditis in children small doses of morphin are valuable and especially so in cases in which there is nervousness or edema.

Dr. Percival Eaton, Pittsburgh, Pa.: In the anemia which frequently complicates these cases I would suggest the longer administration of iron. I think we sometimes keep these children in bed too long. In many cases the heart can be trained to meet the needs of the child; we seem to forget how much can be done by beginning with a very little exercise and gradually increasing it.

Dr. Frank S. Churchill, Chicago: One can get around the long rest in bed by passive exercises. The question of allowing the child up when the pulse is 100 or less depends on the age of the child and the blood-pressure.

Dr. L. E. La Fetra, New York: The family tendency to endocarditis may be explained by the hereditary tendency of lymphoid tissue to infection. The blood-pressure can be used as a guide along with the pulse-rate to determine when the patient may be allowed out of bed. Often for the first few days after the child is up the heart will be rapid; then it will get its second wind, so to speak, and go along all right.

Dr. Herbert Wilcox, New York: One should get these children with anemia and endocarditis into the country. We have a hospital branch in the country, and last summer sent a number of children out there who were under the observation of one of the members of the hospital staff. They received no treatment except good hygienic care, and most of them were permanently improved by this method. This shows why better results are obtained in the families of the wealthy than in those of the poor.

Dr. Floyd M. Crandall, New York: Many children in poor surroundings get hospitalism if kept in bed too long. It is not well to center the child's mind on his heart, and in order to avoid doing this I often make the excuse that I am examining the child for a cough when I am observing the heart. One cannot tell much about the heart unless the child is asleep. The relation of the family history of rheumatism in these cases is interesting. In a family that came under my observation in which there were seventeen cousins, every one had either chorea, endocarditis or rheumatism.

3 Ameboid Movement in Corial Melanophores of Rana. D. Hooker, New Haven, Conn.
4 Weight of Thymus of Albino Rat (Mus Norvegicus Albinus) According to Age. S. Hatai.

1. Erythroblasts in Pig Embryo.—The data derived by Emmel by investigation involving the study of blood-cultures, living and fixed blood-vessels in the pig embryo, together with the observations of other investigations for both red and white blood-cells in various mammals, raises the question whether the origin of non-nucleated erythrocytes by a process of cytoplasmic constriction does not merit more serious consideration. Concerning the prevalent views of nuclear extrusion and intracellular disintegration, Emmel claims that the arguments so far as they are based on the indirect evidence from free erythrocytic nuclei in the circulation, erythrocytic nuclear inclusions in phagocytic cells, and nuclear particles in plastids, do not appear conclusive for either theory, and seem equally well accounted for on the basis of cytoplasmic constriction. Nor is the more direct evidence for nuclear extrusion, at least in the embryo, sufficiently convincing but that the problem appears still to be an open one concerning which the present data for cytoplasmic constriction may be justifiably introduced. The organ of non-nucleated erythrocytes by cytoplasmic constriction, if correct, renders the erythroblasts in this respect comparable with the megakaryocytes, plasma cells and lymphocytes, to which they are apparently closely related genetically, for according to recent investigations these cells normally contribute to the mammalian circulation at least two important non-nucleated morphologic elements other than plastids, by the constriction off parts of their cytoplasm.

5. Free Malarial Parasites.—The malarial parasite is extracellular throughout its life cycle and migrates from one red corpuscle to another destroying each before it abandons it; in the brief intervals between according to Lawson the parasite is free in the blood-serum; it does not remain free long, but almost immediately attaches itself to another red corpuscle by means of delicate pseudopodia. The compact form of the tertian parasite is the type of free parasite most often observed; in this form the parasite may be seen not only in migration, but after quinin and in the cadaver. Lawson believes the compact form to be the normal resting form of the parasite, all other forms being assumed in order to secure attachment and to obtain food, and cautions against confounding free parasites having protoplasmic pseudopodia ready for attachment with the sexual flagellating parasites, whose flagella are composed of chromatin.

The malarial parasite can live for some time free in the blood-serum, though under normal conditions there is no reason why it should remain free for any length of time, and there are certain periods in the life of the parasite when it must be admitted that it is free from the corpuscle and survives. If the parasite is attached to the external surface of the red corpuscle, it is constantly exposed to the action of the patient's serum. The destruction of more than one red corpuscle by each parasite, Lawson says, would readily account for the severe and early anemia occurring in malarial infections. Long continued treatment with quinin will eventually cause the death of all malarial parasites.

7. Ovarian Infection in Domestic Fowl.—Ovarian infection and germinal transmission of disease have been conclusively demonstrated in Rettger's investigations of bacillary white diarrhea in the common domestic fowl. The disease, which has caused so much loss to the poultry industry in recent years, primarily affects young chicks that are but a few weeks old. Chicks which survive frequently become permanent bacillus carriers, the ovary being the important seat of infection. The eggs from such carriers often harbor the organism of the disease in the yolk. Chicks that develop in infected eggs become in turn infected, and have the disease at the time of hatching. The disease is transmitted to normal chicks through the infected droppings; thus an epidemic is produced, and the cycle of infection is completed. There is no evidence to indicate that germinal transmission through the male takes place. In view of the frequent negative results bearing on this question it seems probable that it does not.

11. Recognition of Cholera Vibrio.—Although it cannot as yet be definitely proven Craster believes we are justified in suspecting cholera-like vibrios which eventually develop agglutination properties are of a true cholera nature. It is probable that the production of agglutination and antibodies in the serum brings about the development by the bacterial cell of defensive antiagglutinins, resulting in the disappearance of agglutinating power. In the case of the water vibrios, changed physical conditions could bring about a similar alteration in biologic properties. It may be said that the absence of agglutination in a vibrio isolated from a suspected source does not define conclusively its non-cholera nature. In all probability among a number of cholera-like vibrios isolated from suspected sources a certain percentage will eventually be found to develop agglutination either during laboratory cultivation or by means of animal passage, and until subjected to a procedure that will induce the return of agglutination no vibrio can be regarded with assurance as of a truly saprophytic variety.

13. Production of Precipitins.—By giving rabbits intraperitoneal injections of increasing quantities of serum or blood on three successive days, Hektoen says, a serviceable precipitating serum may be produced in about fifteen days. The same quantity of antigen injected at one time also appears to give good results. The curve of the precipitin in such cases is like the simple antibody curve following a single injection of other antigens. The injection of whole blood may be more advantageous in producing more precipitins for blood-proteins in general than the injection of serum only. The injection of washed human corpuscles give rise to precipitins for human serum.

14. Colon Group of Bacteria.—A collection of typical gas-forming bacteria occurring in milk was obtained by the authors from widely separated and representative sources. These cultures were examined for morphology, spore formation, Gram-stain, amount of gelatin liquefaction, production of indol, reduction of nitrates and neutral red; and amount of acid produced from dextrose, levulose, galactose, adonite, saccharose, lactose raffinose, starch, inulin, mannite, salicin and dulcite. Particular attention was given to the production of gas in media containing dextrose, and for the isolation of this gas the exact method of Keyes with some modifications was used. The carbon dioxid to hydrogen ratio which occurred with the greatest frequency was approximately 1.1. Plotted on the frequency basis this ratio stands apart from all higher ratios. All cultures giving the 1.1 ratio are distinguished from high ratio cultures by the amount of gas formed under exact conditions. This was uniformly less than the amount produced under identical conditions by the high ratio cultures. The amount of acid produced from the individual test substances could not be used to advantage because this was frequently obscured by a secondary alkaline fermentation in which the acid was partially or entirely neutralized. The low ratio cultures fermented a smaller number of test substances than those giving a high ratio, but this difference was not always in those substances usually considered to be fermented with the greater difficulty. The low ratio cultures are distinguished by a high percentage of cultures giving a positive indol test, reduction of nitrates and fermentation of dulcite and glycerin. Very few cultures ferment adonite and starch, and only about 40 per cent. ferment saccharose and raffinose. The high ratio cultures, on the other hand, give a lower percentage of positive test with indol, a much higher number of positive tests with adonite and starch, nearly all ferment saccharose and raffinose but only a few ferment dulcite and glycerin. The low ratio group may possibly be divided into those which ferment dulcite but fail to ferment adonite and starch, and those which do not ferment dulcite but occasionally ferment adonite and starch. No data are available for a logical subdivision of the high ratio group with the possible exception of the small number liquefying gelatin. The 10 gelatin liquefying cultures agreed very closely in the gas ratio, the fermentation of saccharose and glycerin, and the failure to ferment adonite and dulcite. They differed from other high ratio cultures especially in the gas ratio and the fermentation of glycerin. The collection contained a few cultures which differed radically from the others in giving a prolonged fermentation in milk with the production of enormous quantities of gas, and one type which was distinguished by the fermentation of dextrose with the production of carbon dioxid only.

15. **Diminished Coagulation of Blood in Anaphylactic Shock.**—Of 7 dogs developing marked anaphylactic shock, all showed a delay in, or absence of, coagulation of the blood. In all of these the addition of calcium and thromboplastin solution to the oxalated plasma restored its coagulability much more efficiently than calcium alone, or calcium plus fibrinogen solution. No noteworthy change was observed in the fibrinogen content of the blood in this group. The authors believe that such results point to a decrease of thromboplastin or an excess of antithrombin as the important feature responsible for the loss of power of coagulation in anaphylactic shock. Five dogs with slight or no shock showed no changes in the coagulability of the blood, except that in 4 the freshly prepared oxalated plasma (1.10) clotted spontaneously. In no case was clotting observed in richer proportions of oxalate (1.15). The supposition that this coagulation in the presence of oxalate might be due to an excess of calcium in the blood was shown by the result of quantitative calcium determination to be untenable. The only plausible explanation in the authors' opinion is that suggested by the work of MacRae and Schnack, that is, that some thromboplastic substance, as kephalin, may be present and in the absence of an excess of oxalate is responsible for the clotting of the plasma.

17. **Azo-Dyes in Tuberculosis in Guinea-Pigs.**—DeWitt found that trypan blue and trypan red readily penetrate the tubercle in all stages of its development, thus showing that it is possible to penetrate the avascular tubercle by chemicals introduced either subcutaneously, intravenously or intraperitoneally. Trypan blue and trypan red do not penetrate the tubercle bacillus well, and do not kill it in vitro even after twenty-four hours' exposure to a 1 per cent. solution. In therapeutic doses, frequently repeated for long periods, trypan blue and trypan red seem to have no favorable or curative influence in experimental tuberculosis in guinea-pigs. In a single large, nearly lethal dose at the beginning of the infection, they also have no favorable influence. Silver-trypan blue and iron-trypan blue also penetrate the tubercle, but have no bactericidal and no therapeutic influence. It is doubtful whether the metals are carried in with the dye. Copper-trypan blue is soluble, but does not penetrate either the normal or the tuberculous tissues, and is probably changed to an insoluble form or a suspension colloid and retained at the point of injection. Mercury blue is insoluble, is strongly bactericidal in its action on the tubercle bacillus, but is too toxic for therapeutic use, since the pigs died apparently from chronic mercury poisoning rather than from the tuberculous infection, the tuberculous process being generally very slight. The findings with this salt, however, are suggestive, and further experiments with mercury salts will be made.

23 *Pharmacologic Action of Certain Substances on Bronchioles. D. E. Jackson, St. Louis.

20. **Swelling of Colloids.**—No influence to increase colloidal swelling has ever been observed through the action of hydrogen ions varying within the ranges of acidity known to occur in the body or in the urine. A number of investigations make clear the quantitative relationship between hydrogen ion concentration and the swelling of fibrin and of gelatin plates. Such variations in osmotic pressure as may occur in autolysis and in a variety of other ways greatly influence colloidal swelling and also the swelling of bits of fresh kidney. A tendency to acidity in the organism is not commonly accompanied by edema, but is usually quite independent of any known disturbance of the water equilibrium of the organism. Hence it is utterly fallacious to assume that any significance, as a cause of edema, attaches to the frequent occurrences of a tendency to acidity—one of the commonest of pathologic states—in edema. A tendency to acidity of the urine often occurs apart from nephritis and albuminuria. Hence it is fallacious to argue that any significance, as a cause of nephritis, attaches to the frequent occurrence of this very common pathologic condition in nephritis and albuminuria.

21. **Site of Action of Strychnin.**—Strychnin according to McGuigan and Becht acts on both motor and sensory neurons and no tetanus can develop from its action unless the motor neuron is directly acted on by it.

22. **Action of Drugs on Bronchioles.**—Jackson found that arecolin produces immediate and profound bronchoconstriction. This can be readily overcome by epinephrin, etc. Small doses of atropin or hyoscin (or of the so-called duboisin) completely prevent the constrictor action of arecolin. Arecolin is very much more active than pilocarpin both on the bronchioles and on the heart. The action of arecolin tends to pass off much more quickly than that of pilocarpin. Hordenin is a very active bronchodilator. This action depends on a stimulation of the sympathetic nerve endings. It stimulates the heart and produces a moderate, prolonged rise in blood-pressure. It will produce bronchodilatation after constriction has been established by arecolin, pilocarpin, B-iminazolylethylamin or thebain. The dilatation thus produced is usually of a more prolonged and lasting character than that produced by epinephrin. The

rise in general blood-pressure is, however, only about one-fourth to one-sixth as great as that produced by epinephrin. B-iminazolylethylamin produces marked bronchoconstriction of direct muscular origin and which hordenin, epinephrin, "lodal," etc., may or may not overcome, depending on the extent and duration of the constriction and the quantities of the drugs administered. This practically amounts to a pitting of the direct muscular contracting action of the former drug against the indirect nervous bronchodilating action of any one of the latter drugs. The result in any given case will simply amount to the algebraic sum of these two forces. "Lodal" (6.7 dimethoxy-2 methyl-3.4 dihydroisoquinolinum chlorid) produces a moderate bronchodilatation after constriction produced by arecolin, pilocarpin and sometimes by B-iminazolylethylamin. This dilatation is apparently partly (but probably not wholly) due to the liberation of epinephrin from the adrenal glands which has been shown by others to occur. Hydrastinin has a similar but weaker action. B-tetrahydronaphthylamin produces moderate bronchodilatation after pilocarpin, etc. There is also a marked rise in blood-pressure. Thebain produces profound bronchoconstriction. This is of direct muscular origin. It may be overcome to a considerable extent by hordenin or epinephrin. "Lodal" is much less effective. This intense bronchoconstriction is probably rather closely associated with the strychnin like convulsions observed by Magendie, Bernard and others. The amount of the prescribed therapeutic dose appears to be well within the limits of quantities which may be expected to produce distinct bronchoconstriction in the human subject. Ergotoxin possesses no very marked specific action of its own to the bronchioles, either in the way of dilatation or constriction when injected intravenously into spinal animals. And all other drugs tested out (arecolin, pilocarpin, thebain, epinephrin, "lodal," hordenin) act in a perfectly normal manner on the bronchioles after enormous doses of ergotoxin have been injected intravenously. So far as the action of drugs on the bronchioles is concerned the conclusion is reached by Jackson that bronchoconstrictor nerves always respond true to the vagus type, and bronchodilator nerves always react in a manner exactly analogous to that of the visceral thoracico lumbar sympathetics. But the relative extent of these reactions with various drugs may vary through rather wide limits.

23. **Pharmacologic Action of Certain Substances on Bronchioles.**—A new method for carrying on artificial respiration by means of a specially devised piece of apparatus is described by Jackson. This piece of apparatus fits inside the thorax and the lungs are inflated by exhausting the air from the cavity of the chest whose walls are held rigidly in place by the apparatus. Experiments were performed mostly on dogs and cats. It has been impossible to confirm (in these animals) the observations of others that epinephrin produces a preliminary specific bronchoconstriction. Arecolin produces extreme bronchoconstriction. Its action may be overcome by epinephrin, "epinine," etc., or prevented by atropin or hyoscin. The action of arecolin differs in several particulars from that of pilocarpin. Hordenin is a very effective bronchodilator. It possesses this action after constriction has been produced by pilocarpin, arecolin, and sometimes after B-iminazolylethylamin and thebain. It raises the general blood-pressure much less than epinephrin. B-iminazolylethylamin produces marked bronchoconstriction of direct muscular origin which, under certain conditions, may be completely overcome (dilatation) by hordenin or epinephrin. Under certain other conditions these drugs fail to cause dilatation after B-iminazolylethylamin. "Lodal" (6.7 dimethoxy-3 methyl 3.4 dihydroisoquinolinum chlorid) produces moderate bronchodilatation. Hydrastenin has a similar but weaker action. This is probably partly due to liberation of epinephrin. B-tetrahydronaphthylamin produces moderate bronchodilatation (active). Thebain produces profound bronchoconstriction of direct muscular origin. Hordenin, "epinine," epinephrin, etc., are able to overcome this, under certain conditions, to a moderate degree. This bronchoconstriction probably is rather closely associated with the strychnin like convulsions ordinarily produced by thebain. The prescribed therapeutic dose of thebain would appear to be within the limits of quantities which might be expected to cause a fair degree of bronchoconstrictor. Ergotoxin has a mild specific bronchoconstrictor action which is probably of direct muscular origin. After enormous doses of ergotoxin perfectly normal reactions were obtained by the use of all other drugs tested out (i. e., arecolin, thebain, pilocarpin, epinephrin, tyramin, "lodal," hordenin).

34. **Lobar Pneumonia.**—The fifty-four cases of lobar pneumonia cited by Cornwall were treated by a special method. A point in the hygiene which is considered of importance is to temper the cold fresh air to the afebrile patient. During the febrile period of a well marked lobar pneumonia, Cornwall says, the fresh air should be cold, but in the aged and in cases with little or no fever, and always after defervescence, the patient should be kept warm and should be protected from drafts. Careless exposure of the patient when he has no fever may be responsible for complications.

A particular and essential feature of this treatment is the regulation of the diet along the following lines: The quantities of protein and fuel given are less than the minimum health rations; the diet as a whole is non-putrefactive; and it includes a sufficient quantity of the food salts needed by the body, especially the calcium salts, of which a deficiency regularly exists in pneumonia. The purpose of this diet is to supply nourishment sufficient to carry the patient through the short period of this disease with a minimum of trouble from the alimentary tract, that region of special danger in pneumonia, whence may come general poisoning, vasomotor paralysis, nervous disturbances of the heart through reflexes and mechanic disturbances from distension.

Another essential and characteristic feature of this treatment is extreme caution and reserve in the use of cathartics. Castor oil or some other vegetable cathartic is preferred. The popular calomel and Epsom salts are looked on with disfavor by Cornwall, and he believes that the administration of that combination at the beginning of a pneumonia or any time in its course may add materially to the gravity of the prognosis. In this treatment, after an initial gentle purge, simple or soap suds enemas are given every second day if the patient is in good condition, until the expected time of the crisis, which is taken to be the fifth day of the disease; after that time, or at any time if there are signs of heart-strain, the bowels are not disturbed.

The treatment of symptoms according to this method is distinguished by conservatism. If there is severe pain in the early period of the disease, preventing necessary sleep, morphin or codein is given in moderate doses; but later in the disease, and especially near the time of the crisis, and mation, Gram-stain, amount of gelatin liquefaction, production of indol, reduction of nitrates and neutral red; and amount of acid produced from dextrose, levulose, galactose, adonite, saccharose, lactose raffinose, starch, inulin, mannite, salicin and dulcite. Particular attention was given to the production of gas in media containing dextrose, and for the isolation of this gas the exact method of Keyes with some modifications was used. The carbon dioxid to hydrogen ratio which occurred with the greatest frequency was approximately 1.1. Plotted on the frequency basis this ratio stands apart from all higher ratios. All cultures giving the 1.1 ratio are distinguished from high ratio cultures by the amount of gas formed under exact conditions. This was uniformly less than the amount produced under identical conditions by the high ratio cultures. The amount of acid produced from the individual test substances could not be used to advantage because this was frequently obscured by a secondary alkaline fermentation in which the acid was partially or entirely neutralized. The low ratio cultures fermented a smaller number of test substances than those giving a high ratio, but this difference was not always in those substances usually considered to be fermented with the greater difficulty. The low ratio cultures are distinguished by a high percentage of cultures giving a positive indol test, reduction of nitrates and fermentation of dulcite and glycerin. Very few cultures ferment adonite and starch, and only about 40 per cent. ferment saccharose and raffinose. The high ratio cultures, on the other hand, give a lower percentage of positive test with indol, a much higher number of positive tests with adonite and starch, nearly all ferment saccharose and raffinose but only a few ferment dulcite and glycerin. The low ratio group may possibly be divided into those which ferment dulcite but fail to ferment adonite and starch, and those which do not ferment dulcite but occasionally ferment adonite and starch. No data are available for a logical subdivision of the high ratio group with the possible exception of the small number liquefying gelatin. The 10 gelatin liquefying cultures agreed very closely in the gas ratio, the fermentation of saccharose and glycerin, and the failure to ferment adonite and dulcite. They differed from other high ratio cultures especially in the gas ratio and the fermentation of glycerin. The collection contained a few cultures which differed radically from the others in giving a prolonged fermentation in milk with the production of enormous quantities of gas, and one type which was distinguished by the fermentation of dextrose with the production of carbon dioxid only.

15. **Diminished Coagulation of Blood in Anaphylactic Shock.**—Of 7 dogs developing marked anaphylactic shock, all showed a delay in, or absence of, coagulation of the blood. In all of these the addition of calcium and thromboplastin solution to the oxalated plasma restored its coagulability much more efficiently than calcium alone, or calcium plus fibrinogen solution. No noteworthy change was observed in the fibrinogen content of the blood in this group. The authors believe that such results point to a decrease of thromboplastin or an excess of antithrombin as the important feature responsible for the loss of power of coagulation in anaphylactic shock. Five dogs with slight or no shock showed no changes in the coagulability of the blood, except that in 4 the freshly prepared oxalated plasma (1.10) clotted spontaneously. In no case was clotting observed in richer proportions of oxalate (1.15). The supposition that this coagulation in the presence of oxalate might be due to an excess of calcium in the blood was shown by the result of quantitative calcium determination to be untenable. The only plausible explanation in the authors' opinion is that suggested by the work of MacRae and Schnack, that is, that some thromboplastic substance, as kephalin, may be present and in the absence of an excess of oxalate is responsible for the clotting of the plasma.

17. **Azo-Dyes in Tuberculosis in Guinea-Pigs.**—DeWitt found that trypan blue and trypan red readily penetrate the tubercle in all stages of its development, thus showing that it is possible to penetrate the avascular tubercle by chemicals introduced either subcutaneously, intravenously or intraperitoneally. Trypan blue and trypan red do not penetrate the tubercle bacillus well, and do not kill it in vitro even after twenty-four hours' exposure to a 1 per cent. solution. In therapeutic doses, frequently repeated for long periods, trypan blue and trypan red seem to have no favorable or curative influence in experimental tuberculosis in guinea-pigs. In a single large, nearly lethal dose at the beginning of the infection, they also have no favorable influence. Silver-trypan blue and iron-trypan blue also penetrate the tubercle, but have no bactericidal and no therapeutic influence. It is doubtful whether the metals are carried in with the dye. Copper-trypan blue is soluble, but does not penetrate either the normal or the tuberculous tissues, and is probably changed to an insoluble form or a suspension colloid and retained at the point of injection. Mercury blue is insoluble, is strongly bactericidal in its action on the tubercle bacillus, but is too toxic for therapeutic use, since the pigs died apparently from chronic mercury poisoning rather than from the tuberculous infection, the tuberculous process being generally very slight. The findings with this salt, however, are suggestive, and further experiments with mercury salts will be made.

23 *Pharmacologic Action of Certain Substances on Bronchioles. D. E. Jackson, St. Louis.

20. **Swelling of Colloids.**—No influence to increase colloidal swelling has ever been observed through the action of hydrogen ions varying within the ranges of acidity known to occur in the body or in the urine. A number of investigations make clear the quantitative relationship between hydrogen ion concentration and the swelling of fibrin and of gelatin plates. Such variations in osmotic pressure as may occur in autolysis and in a variety of other ways greatly influence colloidal swelling and also the swelling of bits of fresh kidney. A tendency to acidity in the organism is not commonly accompanied by edema, but is usually quite independent of any known disturbance of the water equilibrium of the organism. Hence it is utterly fallacious to assume that any significance, as a cause of edema, attaches to the frequent occurrences of a tendency to acidity—one of the commonest of pathologic states—in edema. A tendency to acidity of the urine often occurs apart from nephritis and albuminuria. Hence it is fallacious to argue that any significance, as a cause of nephritis, attaches to the frequent occurrence of this very common pathologic condition in nephritis and albuminuria.

21. **Site of Action of Strychnin.**—Strychnin according to McGuigan and Becht acts on both motor and sensory neurons and no tetanus can develop from its action unless the motor neuron is directly acted on by it.

22. **Action of Drugs on Bronchioles.**—Jackson found that arecolin produces immediate and profound bronchoconstriction. This can be readily overcome by epinephrin, etc. Small doses of atropin or hyoscin (or of the so-called duboisin) completely prevent the constrictor action of arecolin. Arecolin is very much more active than pilocarpin both on the bronchioles and on the heart. The action of arecolin tends to pass off much more quickly than that of pilocarpin. Hordenin is a very active bronchodilator. This action depends on a stimulation of the sympathetic nerve endings. It stimulates the heart and produces a moderate, prolonged rise in blood-pressure. It will produce bronchodilatation after constriction has been established by arecolin, pilocarpin, B-iminazolylethylamin or thebain. The dilatation thus produced is usually of a more prolonged and lasting character than that produced by epinephrin. The

rise in general blood-pressure is, however, only about one-fourth to one-sixth as great as that produced by epinephrin. B-iminazolylethylamin produces marked bronchoconstriction of direct muscular origin and which hordenin, epinephrin, "lodal," etc., may or may not overcome, depending on the extent and duration of the constriction and the quantities of the drugs administered. This practically amounts to a pitting of the direct muscular contracting action of the former drug against the indirect nervous bronchodilating action of any one of the latter drugs. The result in any given case will simply amount to the algebraic sum of these two forces. "Lodal" (6.7 dimethoxy-2 methyl-3.4 dihydroisoquinolinum chlorid) produces a moderate bronchodilatation after constriction produced by arecolin, pilocarpin and sometimes by B-iminazolylethylamin. This dilatation is apparently partly (but probably not wholly) due to the liberation of epinephrin from the adrenal glands which has been shown by others to occur. Hydrastinin has a similar but weaker action. B-tetrahydronaphthylamin produces moderate bronchodilatation after pilocarpin, etc. There is also a marked rise in blood-pressure. Thebain produces profound bronchoconstriction. This is of direct muscular origin. It may be overcome to a considerable extent by hordenin or epinephrin. "Lodal" is much less effective. This intense bronchoconstriction is probably rather closely associated with the strychnin like convulsions observed by Magendie, Bernard and others. The amount of the prescribed therapeutic dose appears to be well within the limits of quantities which may be expected to produce distinct bronchoconstriction in the human subject. Ergotoxin possesses no very marked specific action of its own to the bronchioles, either in the way of dilatation or constriction when injected intravenously into spinal animals. And all other drugs tested out (arecolin, pilocarpin, thebain, epinephrin, "lodal," hordenin) act in a perfectly normal manner on the bronchioles after enormous doses of ergotoxin have been injected intravenously. So far as the action of drugs on the bronchioles is concerned the conclusion is reached by Jackson that bronchoconstrictor nerves always respond true to the vagus type, and bronchodilator nerves always react in a manner exactly analogous to that of the visceral thoracico lumbar sympathetics. But the relative extent of these reactions with various drugs may vary through rather wide limits.

23. **Pharmacologic Action of Certain Substances on Bronchioles.**—A new method for carrying on artificial respiration by means of a specially devised piece of apparatus is described by Jackson. This piece of apparatus fits inside the thorax and the lungs are inflated by exhausting the air from the cavity of the chest whose walls are held rigidly in place by the apparatus. Experiments were performed mostly on dogs and cats. It has been impossible to confirm (in these animals) the observations of others that epinephrin produces a preliminary specific bronchoconstriction. Arecolin produces extreme bronchoconstriction. Its action may be overcome by epinephrin, "epinine," etc., or prevented by atropin or hyoscin. The action of arecolin differs in several particulars from that of pilocarpin. Hordenin is a very effective bronchodilator. It possesses this action after constriction has been produced by pilocarpin, arecolin, and sometimes after B-iminazolylethylamin and thebain. It raises the general blood-pressure much less than epinephrin. B-iminazolylethylamin produces marked bronchoconstriction of direct muscular origin which, under certain conditions, may be completely overcome (dilatation) by hordenin or epinephrin. Under certain other conditions these drugs fail to cause dilatation after B-iminazolylethylamin. "Lodal" (6.7 dimethoxy-3 methyl 3.4 dihydroisoquinolinum chlorid) produces moderate bronchodilatation. Hydrastenin has a similar but weaker action. This is probably partly due to liberation of epinephrin. B-tetrahydronaphthylamin produces moderate bronchodilatation (active). Thebain produces profound bronchoconstriction of direct muscular origin. Hordenin, "epinine," epinephrin, etc., are able to overcome this, under certain conditions, to a moderate degree. This bronchoconstriction probably is rather closely associated with the strychnin like convulsions ordinarily produced by thebain. The prescribed therapeutic dose of thebain would appear to be within the limits of quantities which might be expected to cause a fair degree of bronchoconstrictor. Ergotoxin has a mild specific bronchoconstrictor action which is probably of direct muscular origin. After enormous doses of ergotoxin perfectly normal reactions were obtained by the use of all other drugs tested out (i. e., arecolin, thebain, pilocarpin, epinephrin, tyramin, "lodal," hordenin).

34. **Lobar Pneumonia.**—The fifty-four cases of lobar pneumonia cited by Cornwall were treated by a special method. A point in the hygiene which is considered of importance is to temper the cold fresh air to the afebrile patient. During the febrile period of a well marked lobar pneumonia, Cornwall says, the fresh air should be cold, but in the aged and in cases with little or no fever, and always after defervescence, the patient should be kept warm and should be protected from drafts. Careless exposure of the patient when he has no fever may be responsible for complications.

A particular and essential feature of this treatment is the regulation of the diet along the following lines: The quantities of protein and fuel given are less than the minimum health rations; the diet as a whole is non-putrefactive; and it includes a sufficient quantity of the food salts needed by the body, especially the calcium salts, of which a deficiency regularly exists in pneumonia. The purpose of this diet is to supply nourishment sufficient to carry the patient through the short period of this disease with a minimum of trouble from the alimentary tract, that region of special danger in pneumonia, whence may come general poisoning, vasomotor paralysis, nervous disturbances of the heart through reflexes and mechanic disturbances from distension.

Another essential and characteristic feature of this treatment is extreme caution and reserve in the use of cathartics. Castor oil or some other vegetable cathartic is preferred. The popular calomel and Epsom salts are looked on with disfavor by Cornwall, and he believes that the administration of that combination at the beginning of a pneumonia or any time in its course may add materially to the gravity of the prognosis. In this treatment, after an initial gentle purge, simple or soap suds enemas are given every second day if the patient is in good condition, until the expected time of the crisis, which is taken to be the fifth day of the disease; after that time, or at any time if there are signs of heart-strain, the bowels are not disturbed.

The treatment of symptoms according to this method is distinguished by conservatism. If there is severe pain in the early period of the disease, preventing necessary sleep, morphin or codein is given in moderate doses; but later in the disease, and especially near the time of the crisis, and at any time if there is much respiratory embarrassment, opiates are strictly avoided. Hot poultices are sometimes applied for severe thoracic pain. For relief of restlessness, sodium bromid is the preferred drug. If delirium incites the patient to get out of bed, physical restraint is strictly enforced. If there is gastric irritability or diarrhea or tympanites, reduction of the diet is the only treatment given. The diet may be reduced to peptonized milk and barley water alone, or barley water alone, or water alone, with the food salts. If stimulation of the heart is needed, it is given according to the following plan. In the aged, in alcoholics, and in patients with preexisting myocardial disease, it is given from the beginning. In young adults with originally healthy hearts it is usually delayed until signs of heart-strain appear, which is generally not later than the fourth day. The first stimulant given is strychnin sulphate, in doses of one-sixtieth grain three to six times a day. If more stimulation is needed, tincture of strophanthus is given in doses of one and a half minim every four hours. The strychnin sulphate is increased on occasion to one-thirtieth grain every four hours, which is the maximum amount of that drug permitted in this disease, and the strophanthus to two or three minims every four hours. In a large majority of cases, Cornwall states, more than this stimulation is not called for, but if it should be required, caffein citrate in doses of 1 to 3 grains every four hours is added. In cases with extremely low blood-pressure, epinephrin is given, hypodermically or by mouth. If there is an obstinately dilated right ventricle, digitalin is given hypodermically, in addition to the other heart stimulants. For extreme dilatation of the right ventricle threatening disaster, Cornwall believes venesection to be indicated. Whiskey, in small doses, is given to alcoholic patients and to the aged if they bear it well.

48. **Significance of Low Blood-Pressure.**—When low blood-pressure is due to the acute infectious diseases, Piersol says, measures should be instituted to promote adequate elimination of the toxins of the disease and to stimulate the flagging heart or failing vasomotor mechanism, as the case may be. When in course of chronic visceral disease low blood-pressure indicates the onset of cardiac weakness, rest, proper food and stimulation of the weakening cardiac muscle must be resorted to. If the hypotension is but the manifestation of some cachectic state, the cause of the cachexia must be removed if possible. When it results from hemorrhage or dehydration of the system due to persistent vomiting and purging, not only should measures be instituted to relieve the underlying cause, but the depleted volume of circulation should be restored and maintained by the use of normal salt solution intravenously, subcutaneously or by the bowel. In the type of case referred to last, in which the low blood-pressure has no definite discoverable cause other than poor hygiene and malnutrition, Piersol has found that much can be done by forced feeding, proper rest, fresh air, cool bathing, properly graduated exercises, and the use of such drugs as iron and strychnin to overcome the anemia and restore the general muscular tone of the individual.

4. **Multilocular Cystic Disease of Pancreas.**—In 1901 Hadley's patient was operated on for an abdominal tumor. On opening the abdomen, a large cyst first came into view. One and a half pints of dark reddish-brown fluid were withdrawn. The tumor was found to be composed of a multitude of smaller cysts congregated to form a large lobulated tumor extending to the right. It shelled out quite easily until the duodenum was reached. The pancreas was therefore ligated at its neck; the head, although very cystic, was left behind for various reasons. The tumor removed consisted of the whole of the body and tail of the pancreas, and measured 10 inches by 7 inches. It consisted in the main of a large number of cysts varying in size, separated from one another by septa of fibrous tissue and a varying amount of apparently normal pancreatic tissue. The cysts were larger at the tail end than at the head end of the organ. The large cyst, which gave rise to most of the physical signs, was at the extreme tail end. It occupied the whole thickness of the tumor in this situation. The fluid from this large cyst contained altered blood and a large quantity of albumin. It had no amylolytic or proteolytic properties. It was alkaline in reaction. The fluid contained in the smaller cysts was colorless and watery.

From January, 1901, until June 6, 1910, this patient was able to work continuously as overlooker in a large steel pen factory. During that time she had needed practically no medical attendance. In July, 1910, when she again came under Hadley's care, she was almost completely confined to bed. She complained chiefly of gradual loss of power in her hand and arms, with numbness and tingling of the fingers. The muscles of the body generally, and especially of the hands and arms, were much wasted. She had a large tumor in the abdomen situated immediately above and extending to the right of the umbilicus. The tumor was recognized as the head and a portion of the neck of the pancreas in a state of cystic degeneration. It formed a prominent mass and displaced the intestines downward and into the left iliac region of the abdomen. The tumor according to the patient had been getting gradually larger for the last two or three years, but much more rapidly during the last two or three months.

It was painless, well defined and slightly movable. A large cyst could be recognized to the left of the tumor, and numerous small tense cysts studded all over the rest of it.

The skin of the chest, abdomen and thighs was curiously pigmented in irregular patches of a dark brown color, producing a piebald appearance. Except that every two or three weeks she had what she called "bilious attacks," the digestive functions were good. These attacks were "bouts" of uncontrollable vomiting; they were unaccompanied by pain or jaundice, and tended to recur more frequently toward the last. The urine, frequently tested, invariably contained a faint haze of albumin, a few granular and hyaline casts, but never any blood or sugar. The Cammidge reaction was positive throughout this part of illness. The course of her illness was, at first, one of rapidly advancing peripheral neuritis, with rapid wasting of the muscles, most marked in the upper extremities. One month later she had very little sensation in her arms or legs. The deep and superficial reflexes were abolished. Soon after this, rigidity followed by contractures commenced in her hands. The fingers became flexed at the interphalangeal joints, and over-extended at the metacarpophalangeal joints. The wrist joints also became overextended.

Toward the end of November, 1910, her condition resembled an advanced case of progressive muscular atrophy with contractures. In the beginning of 1911 the muscular wasting had become extreme. Both legs were immovably contracted, and both hands clawed (*main en griffe*). There was still a little voluntary movement possible in the arms, but complete loss of coordination. She had been quite unable to feed herself or move herself in bed for some time. There was never any jaundice. Sahli's sign was present. The bowels only moved with aperients, and later, all drugs were vomited, only after enemata. During the last two months of life mucous casts were passed in the stools, which were otherwise normal. Liquid food appeared to be well digested; at all events, no undigested fat or other material were seen in the dejecta. During the last few weeks of her illness there was incontinence of urine and feces. At the time of her death, March 30, 1911, no musculature could be felt; she had literally wasted to a skeleton. There was only partial relaxation of the contractures at death. Her mental condition remained clear until the end. The pancreas was removed en masse with the duodenum and gall-bladder attached. The specimen measured 8 inches in length by 6 inches in breadth at its widest part. The greatest circumference of the head was 11 inches. The stump of the neck—all, in fact, to the left of the groove containing the superior mesenteric artery and vein—was converted into a large unilocular cyst.

9. **Value of Mask over Surgeon's Mouth.**—In order to demonstrate the value of a mask over the surgeon's mouth during operations Candler carried out the following experiments with *Bacillus prodigiosus:* With ordinary breathing and quiet speaking no bacilli left the mouth. Coughing for two minutes caused only a few bacilli to be emitted, and these were controlled by a mask of eight layers of gauze, one of four layers being insufficient. Sneezing was shown to be a most dangerous source of infection from the mouth, one sneeze, and that an artificial one, producing 130 colonies of microorganisms in a circle of 3½ inches diameter at a distance of 18 inches. A mask of eight layers is not sufficient to keep back all organisms during prolonged sneezing, although it reduces the infection considerably. There was, however, no growth on a plate exposed to one sneeze through such a mask.

16 Malingering. J. Collie.

10. **Classification of Arthritis.**—The following list of the common manifestations of pathology and their application to joints is quoted by Carmalt-Jones: 1. Senility—osteoarthritis, in part, overworked, malnutrition—contributory to osteoarthritis. 2. Metabolic toxemia—gout. 3. Infective toxemia—acute rheumatism, rheumatoid arthritis. 4. Focal infection—gonococcal, pneumococcal typhoid, purulent arthritis. 5. Granulomatous infection—tubercular syphilitic arthritis. 6. Neoplasms—rare. 7. Trauma—traumatic synovitis. Arthritis in hemorrhagic diseases.

14. **Causes and Treatment of High Blood-Pressure.**—The longer Hall watches cases of arteriosclerosis the less value does he place on drugs in the treatment of this condition. A serviceable group of drugs is that which has an aperient effect. Among these he would give the first place to calomel and blue pill. These preparations are not only useful as aperients, but they also have a very remarkable effect in lowering blood-pressure. A teaspoonful of Epsom or Glauber's salts may be taken in half a tumblerful of warm water before breakfast, or one of the mineral waters be substituted. Next to the aperients Hall places the iodids. He usually employs the potassium salts, but some patients tolerate the sodium salt better. In patients with a syphilitic history the Wassermann reaction should be tried, and, if positive, mercury should be administered, preferably by inunction. Hall would not advise salvarsan in these cirumstances. After a mercurial course potassium iodid may be given in full doses.

At the menopause or in the obese, small doses of thyroid extract, together with a combination of bromid and iodid of potassium, will be found most useful in diminishing weight, lowering tension, and relieving the patient of the flushes and feeling of fulness in the head. If the iodids are badly borne, potassium or sodium nitrite in 1 to 2 grain doses may be tried, but doses up to 5 grains have been warmly advocated. In solution they are unstable, so they are best ordered in chocolate tablets.

In a few cases Hall has found much benefit from the administration of hippurates of ammonia and lithia. The latter is the one he usually employs; 3 or 4 grains may be given daily. The ammonia salt is less powerful; 6 to 7 grains may be given daily. The more powerful and more quickly acting vasodilators, such as amyl nitrite, nitroglycerin and erythrol tetranitrate, Hall reserves for emergencies, chiefly for anginal or dyspneal attacks coming on in patients with high blood-pressure. For the very acute attacks the inhalation of 3 minims of nitrite of amyl on a pocket-handkerchief will often give immediate relief, and its action may be continued by giving 1/100 grain of nitroglycerin. This dose may be increased up to 1/10 grain, i. e., ten times the initial dose. He has found erythrol tetranitrate in doses of ¼ grain most useful in patients who get anginal symptoms on starting to walk. The drug should be given a quarter of an hour previously.

Blood-letting is a remedy which Hall has found of the greatest possible service in certain cases of high blood-pressure. Venesection is indicated where the patient is unconscious and cerebral hemorrhage is feared; also in convulsive cases attended with high tension. In these cases the timely abstraction of from 10 to 20 ounces of blood, according to the severity of the attack and the sex of the patient, will often be attended with a most satisfactory result. Hall emphasizes the value of the sphygmomanometer in cases of coma, as an indication for the employment of venesection; as by this means one is able to distinguish between coma due to hemorrhage and that caused by thrombosis, as in the latter condition blood-pressure is invariably low.

18. **Diagnosis of Pulmonary Tuberculosis.**—Inman is convinced from experimentation that the antihemolytic power of tuberculous serum can be made manifest in a hemolytic experiment by introducing Besredka's antigen into the mixture. He says that repeated positive reactions, especially with a 32-fold serum dilution, in the absence of a positive Wassermann reaction, indicate the presence of an active tuberculous lesion. Repeated negative reactions indicate the absence of an active tuberculous lesion, if cases of under twelve months' duration be excepted.

22. **New Combined Method of Prostatectomy.**—An incision is made into the bladder under spinal analgesia, and as soon as the bladder is emptied of fetid urine, Thomas pours about an ounce of pure tincture of iodin into it, then drains perineally after injecting tincture of iodin through the meatus along the urethra into the prostatic bed. The patient is lying on his back as in the ordinary suprapubic operation during the whole of its performance, the perineal opening being made on the point of the forceps passed transvesically from above, while the legs are simply spread apart in order to see and to cut on the projecting end of the forceps under the skin. The enucleation is done by the forefinger in the bladder, but frequently Thomas passes the other forefinger into the perineal opening to assist the enucleation from below as in the ordinary perineal prostatectomy. The pouring of pure tincture of iodin into the bladder before the enucleation is started he claims is of great importance, because as soon as fresh raw surface is made in the process of enucleation the tincture follows into every hole and corner. The injection of the tincture along the urethra also ensures a cleaner urethra and further floods the freshly made "prostatic bed."

26. **Tetanus Treated with Injections of Phenol.**—In the case cited by Reynolds the wound and the scar were excised and pure phenol was applied. At the same time the subcutaneous injection of phenol was started, 1 ounce of a 1 per cent. solution being given in the right axilla. Under chloroform anesthesia the injections were repeated, the strength of the solution being raised to 3 per cent. The groins and axilla were treated alternately. Chloroform was administered at each injection owing to the spasms produced by the stimulation of the needle-prick. A careful watch was kept for phenol poisoning, but at no time did the patient show any symptoms. The urine retained its normal color throughout.

On the following morning the spasms became very violent, and the child suffered great pain. Potassium bromid gr. xx and chloral hydrate gr. xx were administered four hourly, and the patient became more quiet. On the sixth day cutaneous erythema and slight edema were noticed at the sites of injections, and these were discontinued. The spasms were increasing in violence and frequency, and the phenol solution was again administered on the seventh day. The injections were discontinued on the eighth and ninth days, but were recommenced at 2 a. m. on the tenth. On the thirteenth day the opisthotonos became very marked, and it increased during the following six days. By the twentieth day it had became excessive, although the spasms decreased both in violence and in frequency.

On the same day the opisthotonos suddenly began to diminish, and had entirely disappeared by the twenty-third day. The rigidity, especially that of the abdomen, did not relax for some time; in fact, this did not disappear for about seven weeks. The patient was able to open the mouth slightly about the sixteenth day, and by the eighteenth was eating bread and butter. Improvement continued uneventfully during the next four weeks, and he was discharged cured on the fifty-sixth day. He was seen three weeks later on return from a convalescent home, and was in perfect health. No antitetanic serum was administered.

29 *Wassermann Positive in Infant, Negative in Mother. M. Cassoute.
30 Gangrene of the Foot in Diphtheria. V. Veau and Weber.

29. **Conflicting Wassermann in Mother and Child.**—The reaction was negative in the mother but positive in the nursling. The child showed no signs of syphilis but did not seem to thrive until after it had been given a course of specific treatment. A number of similar cases from the literature are compared with this to emphasize the importance of the Wassermann test for young children, even those apparently normal. It may reveal those liable to develop serious nervous or other trouble late in life which there was nothing to suggest in childhood, the mother and other children apparently free from any taint of syphilis. Cassoute has encountered three cases in which dementia praecox developed about 20, like a bolt from a clear sky, as there had been nothing in the history of the family to suggest syphilis. If proper treatment had been started in childhood—on the basis of a positive Wassermann—irreparable injury of the nervous system might have been warded off.

33 *Grafting Operation to Prepare Orbit for Artificial Eye. (Greffes épidermiques orbitaires devant permettre dans les cas de symblépharons le port d'un œil artificiel.) Magitot.
34 Black Secretion from Sebaceous Glands of the Breast. (Mélanidrose mammaire.) V. H. Torkomian.

33. **Grafting Procedure to Prepare Orbit for Artificial Eye.**—Magitot refers to cases in which the resection has had to be so extensive that there is no pocket left to hold the artificial eye and no material to which a graft can be sutured to make a pocket. He has been quite successful in such cases with a convex, hollow, silver support, flat at the back, with a hole at the rear into which fits a spring. This almond-shaped support is covered with a Thiersch flap at least 5x6 cm. in size. The edges of the flap are tucked into the opening at the back and are held there by the spring. This skin-coated prothesis is then slipped into the orbit, where it forms an adequate support for the artificial eye.

40 Leg Grows Abnormally Long after Tuberculous Knee Process; Two Cases. Savariaud and Roederer.

35. **Modification of Diet Saves Ducks from Epidemic Disease.**—Merklen refers to the disease called *la crampe* which affects ducklings three or four weeks old. Their legs drag and finally they become paralyzed and die of starvation unless they are brought up by hand. A number of cases having occurred on a farm near Paris, he had the feed changed to a greater variety, and no further cases developed. A return to the former monotonous diet was speedily followed by development of new cases, and the epidemic subsided again when the mixed feed was resumed.

41 *Poisoning from Food. (Les infections alimentaires par le groupe du bacille de Gaertner.) A. Zuber.
42 Botulismus. (Le botulisme hier et aujourd'hui.) C. Esmein.

41. **Poisoning from Food Contaminated with Bacteria of Gaertner Group.**—Zuber compares a number of cases of wholesale poisoning from food, including the Cholet poisoning from a *crème royale*, discussed editorially in The Journal, March 21, 1914, p. 939. The symptoms were similar in every respect to those with meat poisoning from the same group of paratyphoid bacilli, but the mortality was even higher; 10 deaths in 38 cases. Sacquépée found a mortality of only 41 in 2,723 cases on record, that is, 1.5 per cent. The interval was unusually short, only two hours; from twelve to thirty-six hours is the more usual interval. Treatment can be only symptomatic, inducing vomiting, rinsing out stomach and bowels, keeping up diuresis by hot baths, hot compresses to the abdomen and saline infusion. In the extremely toxic, cholera-like cases, stimulants for the heart and application of heat are indispensable. The fact that the toxin is apparently not modified by heat renders the paratyphoid bacillus particularly dangerous.

May, XXXIV, No. 5, pp. 553-720

43 *Aneurysms and Injury of Nerves on the Battle-Field. O. Laurent.
44 *Sporotrichosis of the Breast. E. Quénu.
45 *Cecopexy. (Fixation du caecum au tendon du petit psoas.) P. Duval.
46 *Treatment of Injury of the Knee. (Plaies du genou et leur traitement.) L. Hayem.
47 *The Liver with Appendicitis. (Le foie dans l'appendicite.) J. W. Sallis. Commenced in No. 4.

43. **Battle-Field Aneurysms and Injury of Nerves.**—Laurent remarks that aneurysms used to be rarely encountered by the army surgeons but now they are frequent. The smaller size of the bullet facilitates spontaneous arrest of the hemorrhage, but the aneurysm which forms is liable to be mistaken for an abscess, especially as the pressure is so painful that the man clamors for operative relief. The danger of secondary hemorrhage, infection and gangrene is imminent, and the first dressing should be reenforced with elastic bands and splints as if the limb was fractured. Then expectant treatment should be the rule for five or six weeks, as the hematoma might possibly be absorbed, if the pain is not so violent as to demand intervention. Measures to promote collateral circulation, compression under water, baths, etc., may aid the process. It is rarely possible to suture the vessel. A ligature may be necessary before transportation but it favors infection and gangrene; an emergency ligature is indicated rather more for a diffuse aneurysm. He applies an elastic ligature at first, but it cannot be trusted for long. It is applied above and exactly at the limit of the injury to the artery. The pocket is opened and the clots removed with gauze and the hand. The peripheral stump may bleed and this is ligated also, but within the limits of the injury. Then the soft parts are sutured in tiers. Seventeen cases are reported in detail from the Balkan campaigns, with recovery of all but 3. The most distressing are the aneurysms in the neck; in one such case two unsuccessful attempts were made to ligate the injured common carotid before he succeeded and then another hemorrhage proved fatal.

Laurent operated in 18 of the 61 cases of injury of nerves of which he kept records, and he thinks operative treatment should be the rule for injury of a nerve in a limb, supplementing it with massage, hydrotherapy and injections of strychnin in 3 or 5 mg. doses. The results are better when the operation is postponed until all chance of infection is probably past. He describes 41 cases, with the details of his operative treatment when such was applied. The left radial nerve was the one most often injured, and his experience indicates that spontaneous restoration of a nerve is a most exceptional occurrence.

44. **Sporotrichosis of the Breast.**—Quénu adds another to the four cases on record in which women had a sporothrix tumor in the breast, not tender and not adherent to the skin or deeper tissues, resembling more a cyst than a malignant tumor in some of the cases. In others the tumor was as large as a hen's egg and adherent to the skin, hard except at one point, where there was fluctuation, the nipple retracted, the whole resembling a scirrhus. In cases of this type there were generally other lumps elsewhere which aided in the differentiation. In one case on record there was a concomitant cancer in the breast. All the patients were over fifty-seven; there was one man in the group. The subsidence of the tumors under potassium iodid confirms the diagnosis. In Quénu's case the lesion was curetted but was long in healing until iodid was given, when the breast healed rapidly as also an ulceration on the thigh and the lump in the arm promptly disappeared, but the abscess in the back still persists and he intends to hasten its healing by opening it.

45. **Cecopexy.**—Duval gives five plates to show the preferable technic for fastening the cecum to the psoas parvus.

46. **Gunshot, Stab or Crushing Injury of the Knee.**—Hayem analyzes 11 cases with thirteen operations, remarking that the old saying "the less one does, the better one does," cannot be accepted nowadays. For such injuries as these he advocates intervention and the sooner the better, and the prompt and complete recovery in the 2 cases in which he operated the fourth and sixth hours after a bullet or large stab wound severing the tendon of the quadriceps, confirms the advantages of this. The patients were dismissed completely restored the twenty-fifth and twenty-sixth day. Five patients did not regard their injury as serious and did not apply for treatment until several days or two weeks after the injury; 2 were left with a stiff knee and 3 died from the septicemia already installed or suppuration dragging through months. In 4 other cases the operation came the second day; the joint was already infected or the wound extensive and soiled at the time. Partial or total ankylosis could not be warded off, and the patients were in the hospital from 54 to 146 days.

47. **The Liver with Appendicitis.**—Sallis discusses twenty-five cases, pointing out the variety of disturbances liable in the kidney from the toxic and infectious features of appendicitis. There does not seem to be any effectual means of treating appendicular liver trouble. Prophylaxis is the only weapon at our command, removing the appendix before serious damage results.

48 *Treatment of Hemorrhage with Placenta Praevia. A. Brindeau.
49 Weakness of Cicatrix after Extraperitoneal Cesarean Section. S. Delle Chiaje.

38. **Placenta Praevia.**—Brindeau clings still to the obstetrical treatment of hemorrhage from placenta praevia, relying on the rupture of the membranes, the inflatable bag, bipolar version, manual or instrumental dilatation, etc. Surgical treatment is only exceptionally required. The child is generally born prematurely when there is placenta praevia and the mortality is high, 25 to 70 per cent. even in recent statistics. Rupture of the membrane suffices to arrest the hemorrhage in about 50 per cent. of the cases, but this may lead to complications if labor does not follow. The metreurynter is not always easy to introduce with placenta praevia, and it might push up the placenta and separate it completely. Instrumental or bimanual dilatation still has a mortality of 7 or 8 per cent. All of these measures thus have their drawbacks for the mother and all are distinctly unfavorable for the child. If the hemorrhage still continues, the uterine artery can be clamped through the posterior roof of the vagina, or the aorta can be compressed by the hand or rubber-tube wound around the waist. Still another aid is to slip a chair under the mattress so as to raise the woman's pelvis until the venous pressure is less than the intra-uterine pressure, when the hemorrhage stops of itself.

54 Multiple Diverticula of Large Intestine. H. Kohn.
55 Punctate Application of Thermocautery over Entire Erysipelas Area Aborts Attack. (Abortive Erysipelbehandlung.) J. Kumaris.

50. **Behring's Diphtheria Preventive.**—Behring's mixture of toxin and antitoxin, or "TA" as he calls it, is here officially described and the field for its application outlined. A colored plate shows the local reaction to the vaccination with it. The main points of this communication were summarized in the Berlin Letter, June 14, 1913, p. 1896, and May 30, 1914, p. 1738.

52. **Physiology and Pathology of Working in Compressed Air.**—Bornstein states that among the 694 men with caisson sickness whom he has attended, 90 per cent. had it in the form of "bends," that is, intense pains in the limbs, with marbling. The affection generally is transient, but he has known men incapacitated by the resulting chronic changes in the bones and joints. He remarks that in very few other affections have we so clear an understanding of the nature of the trouble as in compressed-air disturbances. They are the result of the absorption of nitrogen by the tissues, especially by fat and lipoid tissues—which include the nervous system—and then the formation of gas-bubbles as the pressure is released and the gas escapes from the tissues. The symptoms from the gas infiltration of the tissues predominate with caisson sickness and those from gas-bubble production in the disturbances in workers in diving bells. The corpulent are more liable to suffer than the lean, and the persons and organs with sluggish circulation suffer most.

In treatment, means to promote the circulation are an important factor, and Bornstein says that physical exercise is the safest and most effectual means to accomplish this. Men who have never experienced any disturbances at their work in compressed air are liable to begin to suffer if anything happens to hamper their circulation, either general or local. A heart or kidney affection or even an acute bronchitis has been known to bring on fatal caisson sickness in men who had been working for months in compressed air without suspicion of injury. Some of the men seemed to become habituated; fully 75 per cent. escaped recurrence among those who kept on working after their first attack of "bends." Gradual changing from the compressed to ordinary atmospheric pressure gives the gas a chance to escape into the lungs and be expelled without production of gas-bubbles. Oxygen helps; he has established by experiments on animals, on himself and on large numbers of workmen that pure oxygen under a pressure of three atmospheres can be borne for thirty minutes, and help in the expulsion of the nitrogen, as this gas diffuses most readily into a gas which contains little or no nitrogen. Stage decompression is aided by return to the compressed air at need, and "bends" is treated with massage and warm baths, supplementary to the inhalation of oxygen.

53. **Hyperglycemia with Obesity.**—Roth found the sugar content of the blood decidedly above normal in 4 of 16 obese patients examined. Alimentary glycosuria followed ingestion of 100 gm. of dextrose in only 3 of the 4 cases, but determination of the sugar content of the blood revealed the latent diabetes in all the cases. Restriction of the intake of carbohydrates was soon followed by marked improvement. Bang's method for determining abnormal proportions of sugar in the blood proved simple and reliable, and Bornstein commends it highly. Three drops of blood are soaked up into a piece of blotting paper, 16 by 28 mm. When dry, 5 c.c. of a boiling solution of potassium chlorid is poured over it (136 c.c. of a concentrated solution of potassium chlorid; 64 c.c. distilled water and 0.15 c.c. of 25 per cent. hydrochloric acid). This coagulates the albumin in the blood while the sugar diffuses in the fluid and the Fehling reaction is applied after half an hour. If this does not precipitate out any suboxids, then the sugar content of the blood is normal (below 0.15 per cent.). A precipitate means hyperglycemia. With four drops of blood a reaction is obtained with a sugar content of only 0.12 per cent. which is the lowest limit of the normal range. When hyperglycemia is thus ascertained, an antidiabetic diet will not only tend to ward off further trouble from the underlying diabetes, but it will tend to cure the obesity. Hyperglycemia is liable to predispose to arteriosclerosis, contracted kidney, cerebral hemorrhage, cataract, eczema, furunculosis and gangrene, so there is every reason to get on its track early and put an end to it by appropriate dieting.

56 *Roentgen Treatment of Goiter. (Behandlung der Strumen und des Morbus Basedowii mit Röntgenstrahlen.) M. Lüdin.
57 *Biologic Diagnosis of Surgical Tuberculosis. G. Wolfsohn.
58 *Pulsating Pleurisy. (Pulsierende Pleuraergüsse.) E. Levi.

56. **Roentgen Treatment for Goiter.**—Lüdin lists and compares 208 articles on this subject, with special reference to exophthalmic goiter. The general verdict with simple goiter seems to be that a cautious trial of the Roentgen rays seems justified in cases of growing parenchymatous struma in the young. Under other conditions it is indicated only when operative treatment is contra-indicated or refused. Roentgen treatment has more of a field with exophthalmic goiter, and experience is accumulating that it has a favorable action on the Basedow goiter in numerous cases, F. A. Stoney regards it as the treatment of the future; only one of her 41 cases failed to show benefit and 14 were entirely cured. A number have reported benefit from this after failure of all other measures. The nervous disturbances and the impairment of the general health are what respond most favorably to Roentgen treatment. Stegmann's patient gained 3.3 kg. in three sittings and 20 kg. (44 pounds) by the seventh sitting, and four others have mentioned gains of from 4.8 to 22.7 kg. in two to four months. Next in order the tachycardia is influenced but more slowly, and the pulse may grow slower in time. Forty-two report that in time the protruding eyes receded entirely in 6; almost completely in 2; very slight protrusion was left in 9; in 14 there was very little change and none at all in 11. Subsidence of every symptom is rare; only eight writers have reported cases under this heading, but gratifying improvement has been reported by a number in proportions ranging from 33 to 100 per cent. Incomplete abortive forms and cases of acute iodin intoxication seem to have benefited from Roentgen treatment in the hands of some, but Lepine's patient did not seem to be affected.

Holzknecht asserts that the length of time required for treatment reflects the duration of the affection before treatment was begun. One patient with exophthalmic goiter for three months, was cured by a three-months' course of treatment; with three others the figures were respectively twenty-four, three and seven months, cured by twenty-two and six-months' courses of treatment. Two others whose Basedow dated from seven and four years were not cured even under eighteen and seven months of treatment. A few instances have been published of return of symptoms after radiotherapy; more numerous are the reports of durable cures, for one to four years. Ledoux urges exposing the thymus as well as the thyroid, and Kuchendorf includes the heart. Among those who denounce Roentgen treatment are Gebele, v. Eiselsberg, Hochenegg, Hahn and Schloffer. Their main objection is that in case an operation has to be done on the goiter later, the changes in the capsule from the radiotherapy interfere with the operation. But Lüdin remarks that time has shown that this interference is not of much moment. A more serious objection is the liability to transformation of the clinical picture into myxedema under too long Roentgen treatment; Wagner, Howell, Holland, Bergonié and Speder have each reported a case displaying this tendency. Zimmern, Raymond and Gilmer witnessed aggravation of the Basedow in 4 cases. Lüdin says in conclusion that the voices raised against Roentgen treatment are less numerous than those advocating it, but all agree that extreme caution is necessary.

57. **Biologic Diagnosis of Surgical Tuberculosis.**—Wolfsohn's article is based on 264 articles in recent literature discussing serologic findings, the tuberculin reactions and inoculation of animals as aids in differential diagnosis of surgical tuberculous affections. As there is comparatively

little toxic destruction of albumin with localized tuberculous processes, there is little or no instigation to production of antibodies, and hence such processes scarcely ever respond to ordinary serodiagnostic measures. More instructive are tests for opsonins, test transmission of anaphylaxis, and the meiostagmin reaction. These three technics are comparatively reliable but require such skill that they are beyond the reach of most.

The reaction at the focus after subcutaneous injection of tuberculin is extremely instructive, but a number of instances are on record in which this reaction seemed to have contributed to the spread of the disease. Pankow was led to assume bilateral disease from the pain coming on in each kidney after the test subcutaneous injection. The course of the case later proved that one was sound at the time. Krönig has never witnessed a focal reaction with less than 1 mg. of "old" tuberculin, and more than this dose he regards as dangerous. Hohlweg had hematuria in one case; Kremser has reported the flaring up of a latent process in one case—the apparently sound testicle suppurating; Schröder, suppuration around the rectum and epididymitis; Wegner, inflammation of the ribs, while Stricker has compiled a number of instances of prolonged reactions in children with aggravation of the disease or flaring up of old latent foci, generally in lymph-nodes, and acute exacerbations which proved fatal.

It is impossible to foretell any special general or local excessive susceptibility, so that Sahli and some others denounce the subcutaneous tuberculin test altogether. In Diem's two cases the joints swelled and endocarditis developed in one, and he thinks there can be no doubt of the tuberculous nature of this "articular rheumatism" which developed immediately after injecting 0.5 or 1 mg. of tuberculin.

The Pirquet skin tuberculin reaction is more constant and more intense with surgical than with pulmonary tuberculosis, unless the bone process is in the fungous, walled-in stage. This applies also to lupus; a positive reaction can generally be obtained only by applying the tuberculin directly to an opening made in the lupus patch; then an intense focal reaction becomes evident. According to the evidence to date a positive skin tuberculin reaction in children under 2 is a sign of active tuberculosis in every case. With children up to 10 or 12 it suggests a probable surgical tuberculous affection. A negative reaction, especially when repeated, renders the latter improbable.

58. **Pulsating Pleurisy.**—Levi gives brief summaries of 118 cases of pulsating pleurisy which he has found on record. The left side was the seat of the pulsating effusion in 93.6 per cent. of 110 cases, and 77.4 per cent. of 84 cases were in men. In the 45 cases in which the cause was known tuberculosis was incriminated in 55.5 per cent., pneumonia in 15.5, and in one case each, cancer, puerperal pyemia, influenza, polyarthritis and aneurysm, in 3 cases each, trauma and scarlet fever, and twice pneumococcus empyema. The outcome is known in 74 cases: 43.2 per cent. terminated in recovery; 10.8 were improved, 1.4 showed no change and 44.6 per cent. of patients died. The figures make a better showing in the 24 operative cases: recovery in 66.6; improved 12.6, and died 20.8 per cent. No attempt at operation was made in 44 purulent cases and 25 per cent. recovered and 61.3 per cent. died. If the effusion is not purulent medical measures should be given a thorough trial. If they fail the effusion should be aspirated by simple tapping. With a purulent effusion, no time should be lost before resecting ribs for thorough drainage of the pleural cavity. Any delay is dangerous not only on account of progressive debility but to ward off pericarditis.

68 Friedmann's Remedy for Tuberculosis; Reply to Kraus in No. 19. L. Brauer.

61. **Salvarsan in Progressive Paralysis.**—Runge states that remissions worthy of the name occurred only in 3.9 per cent. of 380 cases in which no treatment had been taken; in 9.3 per cent. of 140 treated with iodid alone; in 11.4 per cent. of 35 with mercury alone; in 14 per cent. of 44 treated with a total dosage of 1 gm. salvarsan, and in 60 per cent. of 47 treated with a larger dosage of salvarsan, ranging from 1 to 10.5 gm. These figures speak in favor of salvarsan treatment, especially as the proportion of remissions increased with the dosage, from 28 per cent. among 72 given less than 3 gm. to 74 per cent. in the 19 given over 3 gm. The general health improved remarkably as a rule, even when the mind showed no special improvement. Full earning capacity to date was restored in 11 per cent. including some whose mind had shown impairment for several months. In general, however, results were better the shorter the interval since the first mental symptoms.

The best technic seems to be by repeated courses, bringing the total dosage up to 5 or 10 gm. At the same time Runge warns that entirely refractory cases are sometimes encountered. His experience has shown further that large doses may in some cases fail to induce a remission and the disease may grow more severe and terminate fatally. He gave the salvarsan at five-day intervals but some recent experiences warn that an eight-day interval would be safer. It is often impossible at present to differentiate with certainty between cerebral syphilis and paresis, which renders it all the more necessary, he declares, to treat the patient vigorously with salvarsan at the first onset of symptoms, testing the tolerance cautiously. The paralysis did not seem to be modified by the salvarsan in 42 per cent. of the cases, and in 4 cases the course of the disease seemed to be accelerated although the dosage had been only 0.2 to 1.5 gm. Possibly, better results might have been attained finally if the medication had been pushed farther.

64. **Acute Ileus from Spasm.**—Fromme reports two cases of ileus in which the laparotomy disclosed a spastic constriction as the cause of the trouble. He knows of only twenty such cases on record, exclusive of lead-poisoning cases. The first patient was a boy of nearly 12; the severe pain came on suddenly during a running race. The small intestine was found contracted over quite a stretch, and pale; the entire small intestine was rather small. During the operation the contraction subsided and there were no further disturbances or pain. The second patient was a woman of 55, and in this case also the laparotomy, done on assumption of mechanical ileus, put an end to the spasmodic contraction and all trouble ceased. The woman's small intestine was contracted over a stretch 10 or 20 cm. long at four different points. The patient had broken several ribs four days before the spastic ileus came on. The spastic contraction liable to follow a laparotomy is probably of this same class of cases, all traceable to some injury of the intestines from within or without. Morphin and atropin are the main reliance in treatment, but unless one is certain of the spastic nature of the trouble it is dangerous to give morphin with ileus as liable to mask the clinical picture. The spastic contraction may be the precursor of invagination and may outlast it. This occurred in a case in his experience, the infant dying from the persisting contraction after the invagination had been corrected by a laparotomy. In two other cases a girl of 8 and a young man had several stretches of intestine contracted and the bowel was found invaginated at two or more points. The young man's appendix had been removed for an abscess a few months before and the child had been taken suddenly sick after eating nuts. The laparotomy for

the ileus in each case was followed by complete recovery. There had been no blood in the stools in either case and no adhesions had developed.

65. **Secondary Anesthetic Fatalities.**—Keil has been analyzing and classifying 4,000 cases with general anesthesia given by various technics. There was no immediate fatality in any instance for which the anesthetic could be incriminated, but there were ten deaths which he thinks were the direct result of later injury from the anesthetic used. The first symptoms were observed the second day, with death the fourth day. The patients were between 38 and 61. His experience testifies to the smaller amount of anesthetic required when a mixing apparatus is used instead of the drop method. Preliminary scopolamin-morphin did not display any advantage over the ordinary technic in respect to lesser requirement of the chloroform and ether. The exact figures of the average amount of anesthetic used with each method for the total 4,000 cases are cited.

69. **Whooping-Cough.**—Feer gives statistics which show that whooping-cough is twice as deadly as measles for young infants and six times deadlier than diphtheria (Bavaria, 1893-1902). The Basel statistics show that young infants contracted whooping-cough five times more than measles and scarlet fever and nearly ten times more than diphtheria (1875-1891). Whooping-cough maintains its lead in prevalence over the other diseases up to the age of 5. In 1903 there were 14,000 deaths from whooping-cough in the German empire, the same figure as for diphtheria. And yet, with all this experience, it is still a question whether whooping-cough is contagious during the whooping state or not. In Feer's own experience the institutional epidemics always originated from cases that had not reached the whooping stage. Weill of Lyons thinks that after one week of the paroxysmal cough at farthest there is no more danger of infecting others. He analyzed 104 cases very carefully from this standpoint, and his experience since has confirmed his view that isolation is unnecessary as a rule at this stage. The assumption that contagion occurs only during the catarrhal stage explains why the disease runs through a family but why there is so seldom contagion after the whooping child has entered the hospital while an epidemic is almost certain to develop if a child in the catarrhal stage enters the hospital and begins to whoop later. He has never known of an instance of contagion from clothes or from sleeping in a room after a whooping-cough patient. Direct contact seems indispensable. Healthy carriers may play an important rôle. He says that no remedy has proved its usefulness but that much can be accomplished by tranquilizing the patient. Sometimes replacing an over-anxious nervous mother with a well-poised and capable attendant may have a remarkable influence for the better.

75. **Thyroid Treatment of Chronic Joint Disease.**—Gara reviews what is known of chronic joint affections developing on a basis of metabolic disturbances, gout, gastro-intestinal derangement, etc. He has encountered a special group of cases of chronic joint disease accompanied by various symptoms suggesting neurasthenia and disturbance in the genital sphere besides the rheumatic joint affection. Closer study of this group of cases during the last three years has shown that the thyroid is always more or less enlarged. Discovery of this suggested that abnormal functioning on the part of the thyroid might affect the functioning of the ovaries. This assumption explained at once all the different symptoms observed, from the nervous palpitations and restlessness to the amenorrhea or dysmenorrhea, all of which had proved refractory to ordinary measures. The evidence which Gara presents makes a good plea on behalf of the thyroid origin and necessity for treatment on this basis in a certain proportion of cases of chronic articular rheumatism. He has encountered 132 cases of the kind, all but 11 in women from 16 upward; 43 were over 45. This "thyroid" group formed about 20 per cent. of his cases of chronic "rheumatism" of the joints. He practices at a spa, and consequently sees the patients only while they are taking the waters, so he has no opportunity to apply treatment on these premises. He urges general practitioners to be on the lookout for such cases and to give them systematic thyroid treatment on the above basis.

80. **Shape of the Stomach with Exaggerated Vagus and Sympathetic Tonus.**—Klee gives a number of skiagrams to show the typical changes in the shape of the stomach of cats when the nerves connected therewith were subjected to cold or to heat or were severed.

81. **Cancer Extract in Treatment of Malignant Disease.**—Lunckenbein states that the theory of the protective ferments has explained the unmistakable benefit derived from intravenous injection of cancer extract. The general health improves even in advanced cases, and many inoperable growths have retrogressed until they could be successfully removed. With no other method of treatment to date do the patients show such a remarkable and speedy change for the better as with this tumor-extract treatment. The serodiagnosis after this tumor-extract treatment may show when the cancer has actually been conquered or whether merely transient improvement has been realized. As this method of treatment is a kind of vaccination, the production of the protective ferments being the task of the organism being treated, the technic and estimation of the progress of the case are not always easy. He uses mammary cancer extract, having found that the outcome was apparently the same whether the patient's own cancer material or that from another person was used; the nature of the cancer also seemed to be immaterial. The course of treatment must be

long and persevering. He has sometimes noticed that after a certain length of time the organism seems to have reached the limit of its capacity for protective-ferment production, and the case enters on a stationary phase or begins to go down. When this happens, every effort must be made to raise the tone of the general health so that it can go on with its ferment-production task. Remarkable results are sometimes accomplished in this way. Lunckenbein practices at Ansbach, and his statements are based on his experiences in forty cases.

83. **Epidemic of Poliomyelitis in Orphan Asylum.**—There were only five cases, but four developed practically all on the same day and three of the children were isolated at once. The symptoms were so mild that they were not recognized at once in the fourth child and it was not isolated until the fifth day. The fifth case developed three weeks later and evidently from contact with the case that had been unrecognized at the very first. Only one of the children has entirely recovered; the others still have more or less paralysis.

88. **Treatment of Tuberculosis with Friedmann's Remedy.**—Schittenhelm and Wiedemann report from the medical clinic at Königsberg 40 cases of various forms of tuberculosis in which they have applied Friedmann's remedy, supplied to them free of charge. They review the history of the remedy to date and give full details of their 40 cases. One patient was a man of 32 with Addison's disease who was given the *Simultaninjektion*—as advised by Friedmann in a letter. The temperature ran up to 104, the pulse to 110, and the patient vomited incessantly and rapidly grew weaker, dying the third day. This unfortunate occurrence, they state, was unmistakably the consequence of the febrile reaction to the injection which the debilitated organism was not able to stand. In the 25 cases of pulmonary tuberculosis there was no improvement in the objective findings but 5 showed a relative improvement, the temperature dropping, the amount of sputum growing less in some and certain subjective symptoms and the general health showing some benefit. On the other hand, a much larger number of patients showed no influence from the treatment and 9 grew constantly worse, including 2 in whom the condition became aggravated directly after the injection. A favorable influence was apparent in 3 cases of tuberculous rheumatism of the Poncet type and in a few cases of tuberculous joint processes, the patients showing rapid improvement, notwithstanding the suspension of all other measures. Tuberculous processes in the kidneys were apparently not influenced in the least. Previous treatment with another kind of tuberculin did not seem to affect the action. Friedmann declares that cases in which some other tuberculin has been given often prove refractory to the first injection of his remedy; they display no essential improvement after the first injection but do after the second. This should be given after an interval of four or five weeks. One of the cases here reported was treated on this advice and the second injection had an absolutely aggravating deleterious influence.

They add: "To the question whether the Friedmann remedy is superior to other specific measures for treating tuberculosis the answer according to our results can be only in the negative. We believe positively that the few apparently favorable results which we have to chronicle in pulmonary tuberculosis and Poncet could have been attained with other measures. But we regard the dangers of the treatment as so great that we shall not apply it further. (*Wir halten die Gefahren der Behandlung für so gross, dass wir sie nicht weiter üben werden.*) This judgment is not qualified by the favorable result in the 3 joint cases. Such observations call for experimental following up of the subject; but they cannot justify the further therapeutic application of the remedy which has won disrepute in the majority of the cases by its failure to benefit and its harmfulness."

91. **Keeping Pneumonia Patients out of Bed.**—Widmer relates that ten years ago at a conflagration in a village the men fighting the fire were so chilled and exhausted that between the ninth and thirteenth days thereafter eight developed extremely severe pneumonia, delirious from the first day. As the distances between the farms were so great he was unable to spend much time with any one patient, and the families were in great distress with their delirious sick men. To aid them in tending the sick at night, Widmer had the sick men dressed and allowed to be up at night. To his surprise he found that great improvement in the delirium and in the condition generally followed as soon as the men were thus dressed and up. Analyzing the conditions convinced him that the subconsciousness called into play by the acts of dressing, walking about and especially by rocking in a rocking chair, steadied the higher brain functioning and this in turn steadied and regulated the blood-pressure and other vital processes. Since that time he has made a point of thus calling on the subconsciousness in treatment of pneumonia and has found it a great help in fifty-two cases thus treated. He compares conditions to the difference in the case when water is poured into a glass held in the hand in a moving railway car; it can be poured without spilling, but if the glass is standing on a solid table, it is almost impossible to pour the water into it without spilling.

96. **Experimental Epileptiform Seizures.**—Karplus found in experiments on dogs and monkeys that slitting the corpus callosum its entire length did not prevent general epileptic convulsions when weak electric stimulation was applied to some circumscribed area of the cortex.

99. **Albumin in the Sputum.**—Melikjanz summarizes ten cases of pneumonia to sustain his previous statements in regard to the importance of quantitative estimation of the albumin in the sputum. The later it appears and the later it disappears again, the graver the prognosis. The amount is also proportional to the severity of the lung affection. Large amounts long persisting speak for tuberculosis.

105. **Friedmann's Remedy for Tuberculosis.**—Friedländer reports the case-histories of eight children with tuberculous bone or joint affections in his service given the Friedmann treatment by Friedmann's assistant. A general reaction was observed in all, but it was slight in three cases. The other children had a very considerable temperature reaction and impressive tachycardia, and their subjective reaction, especially the following night, could not be lightly regarded. There was no local reaction but no benefit of any kind followed. The hip-joint disease in one case grew worse but Friedländer does not ascribe this directly to the Friedmann remedy so much as to the neglect of the old and tried orthopedic fixation which was omitted in hopes of benefit from the Friedmann remedy. He exonerates the remedy also from any share in the development of facial paralysis soon after its application in a case of spondylitis. He is confident, however, that the remedy did not display the slightest specific efficacy in his eight cases; and he will decline to use it further even if the objections recently raised against the constancy and purity of the remedy are dissipated.

This communication supplements several others presented at the meeting of the Vienna Medical Society, May 15, of

[illegible] Medical College

the ileus in each case was followed by complete recovery. There had been no blood in the stools in either case and no adhesions had developed.

65. **Secondary Anesthetic Fatalities.**—Keil has been analyzing and classifying 4,000 cases with general anesthesia given by various technics. There was no immediate fatality in any instance for which the anesthetic could be incriminated, but there were ten deaths which he thinks were the direct result of later injury from the anesthetic used. The first symptoms were observed the second day, with death the fourth day. The patients were between 38 and 61. His experience testifies to the smaller amount of anesthetic required when a mixing apparatus is used instead of the drop method. Preliminary scopolamin-morphin did not display any advantage over the ordinary technic in respect to lesser requirement of the chloroform and ether. This communication supplements several others presented at the meeting of the Vienna Medical Society, May 15, of

32500
[illegible]

which a full report is given in the Society Proceedings Department of the *Wochenschrift*. All report "no benefit" and some describe actual harm done by the remedy. It had been administered in all cases by Friedmann himself. One of Bachrach's 5 patients had an isolated mild chronic tuberculosis of one kidney. After the Friedmann remedy had been given, the bladder lesions progressed rapidly and became much aggravated, and the kidney showed a fresh miliary eruption when it was finally removed after waiting three months for any possible benefit from the treatment. The conditions in this case were the most favorable possible, but aggravation rather than benefit was all that was realized. No benefit was observed in the other urogenital cases.

Jungmann reported similar discouraging results in 8 cases of lupus; no benefit has been apparent in the four or five months to date and in 3 cases the lupus has spread materially, the new patches promptly ulcerating. (A few of these cases were treated by Friedmann's assistant.)

Kovacs reported 7 cases of pulmonary tuberculosis. The course was not modified for the better in any instance. One patient died two weeks after the intramuscular injection and a subacute and acute miliary tuberculosis was found in the lungs and some other organs. He called special attention to this case as several others are on record in which this was observed, although it is of course impossible to prove any connection between the remedy and the miliary tuberculosis developing later.

Neumann commented on the way in which Friedmann in determining the indications pays heed only to the subjective symptoms and ignores the stage and extent of the tuberculous process. This rendered particularly noticeable the experiences in Ortner's service in that the subjective disturbances became much worse after injection of the Friedmann remedy. There was but slight reaction to the intramuscular injection (2 cases), but in the 6 intravenously injected cases severe injury followed. The temperature ran up to 104 F. in all and still higher in one (40 and 40.5 C.) and kept at this height for three days, accompanied by intensely severe headache, vomiting and brain symptoms. At the same time severe degeneration of parenchymatous organs was evident; the liver and spleen became much enlarged and tender; there was pronounced urobilinogenuria but elimination of galactose kept within normal range. In one case there was pronounced jaundice; in another subicterus of the conjunctiva. Albuminuria was evident in nearly every case; with tube-casts in one. The muscles became also intensely sensitive to contact, especially in the calf. The appetite was also poor for months, and for weeks there were repeated nausea and vomiting. All complained for months of a dull headache. The heart seemed to feel the deleterious effect most. The blood-pressure dropped 20 or 30 mm. mercury, and did not return to normal for two weeks. The heart became dilated, and systolic murmurs over the initial valve are audible, accompanied by palpitations and pains in the heart—all these symptoms persisting unmodified by valerian or bromids during the five months to date, and influenced only by strophanthus or digitalis. One elderly woman with a goiter had never had cause to complain of her heart before, but after the Friedmann injection she developed a perpetually irregular pulse with extreme weakness of the heart, edema in the legs, and cyanosis, requiring camphor and a course of digitalis, and the heart has not recuperated since.

In short, Neumann concluded, speaking for Ortner, the remedy is not so harmless as Friedmann would have us believe. The tuberculous processes were aggravated and injury of parenchymatous organs was evident, persisting for months and affecting the vital organs. The application of the remedy should be absolutely denounced.

Büdinger reported no benefit in his 4 cases and considerable aggravation in one. Föderl had negative results in all but one of his 5 cases. Nephrotomy had been done before the injection in this case and the operation was more than probably responsible for the improvement that followed. Improvement was noticed after the operation alone in a similar case not given the Friedmann treatment. In one case the injection was followed with fever, rapid pulse, vomiting and diarrhea.

108 *Thick-Film Technic for Microscopic Work in Differential Diagnosis. P. Bosco.

106. **Fat Tissue Necrosis in and Around the Pancreas.**—Verdozzi has recently encountered a case of acute hemorrhagic pancreatitis and one in which there were only minute foci of fat necrosis in the interstitial tissue of the pancreas. He gives a colored plate of the findings and reviews the history of fat necrosis in this region and discusses the pathologic anatomy and syndrome. The attack came on before breakfast in one case; in the other after a hearty meal. In the latter case there was a history of recurring attacks of abdominal pain and vomiting, subsiding after a few days, and the pancreas showed signs of chronic inflammation. The temperature was subnormal in both the women; they were 68 and 78 years old and the first died in three, the other in thirteen days. The localization of the pain in the epigastrium and the meager findings on palpation in contrast to the grave general condition and distress, pointed to pancreatitis. The various hypotheses advanced to explain the fat necrosis are compared; Bignami's theory that the trouble is analogous to a peptic ulcer has much to sustain it.

108. **Thick Films in Microscopic Diagnosis.**—Bosco lauds the thick film technic as a great aid in diagnosis of malaria and relapsing fever.

109. **Endemic Adenomycosis.**—Dias here gives the description of the fungus causing the affection to which he called attention recently, as summarized in The Journal, May 30, p. 1765. He has named the fungus the *Adenomyces cruzi.*

110. **Yellow Fever.**—Valladares gives a number of reflections and suggestions based on the most recent progress in medicine which has thrown light on the symptoms seen in the yellow-fever syndrome for which the ductless glands are responsible. There is much evidence to show that, the acute phase once past, the acutely defective or perverted functioning of the adrenals in particular dominates the clinical picture. Treatment should aim to restore the lacking internal secretion. He proposes therefore as the logical treatment of yellow fever, venesection and saline infusion, lumbar puncture and the usual measures for revulsion. The usually early insufficiency of the liver should be combated with alkalines, sodium benzoate, ether and cold enemas twice a day. As soon as there are signs of defective adrenal functioning, epinephrin should be given systematically. This should be followed by serum from the renal vein of the goat, according to Teissier's technic (described in The Journal, Nov. 14, 1908, p. 1738), when symptoms suggest uremia or impending anuria. Still another measure to be systematically applied is baths if the temperature goes above 39 C., with other symptomatic measures as needed.

THE SERVICE OF MEDICINE TO CIVILIZATION *

VICTOR C. VAUGHAN, M.D.
President of the American Medical Association
ANN ARBOR, MICH.

Fellow members of the American Medical Association: I wish to express my appreciation of the honor conferred on me in being called to officiate as your President at this time. I had been content to serve in the ranks, and I have regarded this position as too honorable to be sought, or to be lightly regarded when spontaneously bestowed. During my term of office I will give you my most devoted service.

In ancient times, civilization was born, grew for a few generations and fell into decay. In all instances it was local and covered only small areas. Its habitations were oases in the world-wide desert of ignorance and superstition, and after an ephemeral existence all were buried in the sand. Relatively small bodies of men occupying salubrious regions developed the elements of science and for a few centuries flourished. Their superior knowledge gave them dominion over their less fortunate neighbors, who were converted into slaves. Conquest brought disease and the local civilizations were obliterated by contagion. History is replete with instances in which triumphant heroes have brought to their rejoicing countries with their prisoners of war invisible and intangible agents of death, which have ultimately vanquished the victors.

The Egyptians of the Pharaohs drained the land, built aqueducts, disposed of their dead hygienically, reared temples and cities, maintained law and order, developed the elements of literature and science and devised and employed simple machinery. In speaking of the ancient Egyptians, Diodorus says: "The whole manner of life was so evenly ordered that it would appear as though it had been arranged by a learned physician, rather than by a lawgiver." Herodotus declared ancient Egypt the healthiest of countries, but filled with physicians of whom "one treats only the diseases of the eye, another those of the head, the teeth, the abdomen or the internal organs." Writing of a later time, Gibbon said: "Ethiopia and Egypt have been stigmatized in all ages as the original source and seminary of the plague." It is evident that in the time of its great civilization Egypt was salubrious; coincident with the decline in the learning and wisdom of its people, it was visited and desolated by pestilence. That Egypt had lost its salubrity as early as the period of the exodus of the Israelites is shown by many passages in the Bible in which the chosen people are threatened with the diseases of Egypt if they neglect or violate the laws. Moses, "learned in all the wisdom of the Egyptians," codified his sanitary rules and regulations in the form of religious rites and ceremonies and thus secured their observance among the faithful even down to the present time.[1]

The Greek developed the most glorious civilization of antiquity because he was the most ardent student of science, but he was unable to cope with malaria and bubonic plague, and his descendants have been in bondage to malaria for nearly twenty-four centuries. The medicine of Hippocrates, the wisdom of Socrates, the philosophy of Plato, the plays of Aristophanes, the laws of Pericles and the science of Aristotle could not save the Greek from the degrading effects of disease, and under its withering influence the civilization of this great people slowly but surely decayed. Its matchless marbles were thrown into the waste, its magnificent temples were allowed to crumble, its altars were deserted, its literature became insipid, its philosophy lost its virility, its science was forgotten and the children of this blighted civilization were sold in the slave markets of Rome and in later generations paid tribute to the Slav and the Turk. There certainly were eminent Greek scientists and physicians for centuries after Hippocrates, but they were not products of Greek soil. They developed in Asia Minor, Egypt, Italy and elsewhere. It is of interest to note in this connection that malaria, according to Jones, was introduced into Greece in the fifth century, B. C., and the fourth century showed the decline of Hippocratic medicine. Neuburger says: "The sons and grandsons of Hippocrates, as well as his immediate disciples, Apollonios and Dexippos, were at the head of that series of physicians who laid emphasis upon theoretical conjecture and gave to medicine in the fourth century B. C. its speculative coloring." Taken with the fact that other departments of learning showed similar retrogression at the same time, this sequence between the introduction of malaria and the trend of medicine toward speculation is worthy of record. That pestilence aided the barbarians in the final desolation of Greece is indicated by the following quotation from Thumb:

> At a time when the German tribes began moving, that is to say, at the end of the third century A. D., a gradual immigration of Slavonic tribes into the Balkans began; their

* President's address before the American Medical Association, at the Sixty-Fifth Annual Session, Atlantic City, June, 1914.

[1] Neither the papyrus of Ebers nor that of Brugsch throw any light on the problems discussed in this article. Indeed the value of both these papyri was at first overestimated. They are now regarded as compilations and consist largely of lists of remedies and furnish no information concerning epidemics or their effects upon the people, except to indicate that hookworm or bilharzia infection, one or both, at that time (about 1500 B. C.) afflicted the Egyptians. These parasites may have contributed to the deterioration of the people; this is a suggestive possibility.

invasions became more and more frequent, since the Goths chose Western Europe as the goal of their conquering expeditions and left to the Slavs an open passage into the Balkan countries. But a real Slavonisation of some Greek territories took place only in the eighth century, and attained its highest point when a horrible plague in 746 depopulated the Greek territories.

I am aware of the fact that some have objected to considering the present inhabitants of Greece as descendants of ancient Greeks. The former have been designated as "so-called Greeks," "a bastard people," "a mosaic of Vlacks, Arnauts and Slavs." Some years ago Fallmerayer made the very positive statement that "no drop of ancient Greek blood flows in the veins of the modern Greek." Thumb has shown the absurdity of these statements and declares that cranial measurements, local names, customs and religion show that while some admixture with the Slav has taken place, the modern Greek is a lineal, and on the whole a fairly pure descendant of those who established the greatest civilization of antiquity. Modern Greek Christianity is only a modification of ancient Greek paganism, in which gods have been supplanted by saints. "Charon the old ferry-man in the underworld is to-day the god of death; he conducts the souls in a dreary procession to his realm. As in antiquity, a copper coin is put into the mouth of a dead person as a fee for the ferry into the other world. The ancient Moirai or fates (to-day, Mires) still determine the fate of the new-born child, spin and cut the thread of life. The bride is conducted into her new home, the dead are buried with ceremonies which the Greeks used already two thousand years ago. A sick person seeks recovery by laying down to sleep in the church of a saint, like those persons who once made a pilgrimage to the temple of Asklepios in Epidaurus. The Greeks of to-day are descendants of the ancient Hellenes, not in the sense in which every modern Greek ould trace his origin back to an ancient Athenian or partan, but in the sense that in the modern people ancient blood flows largely and in some districts almost purely, and still more in the higher sense that the modern race shows a development of the Greek population of the ancient world."

The broken remnants of older civilizations found refuge and asylum in the salubrious climate of the Italian peninsula and soon its hillsides were covered with vines and olives while its plains and valleys bore abundant harvests. Rome was built and her empire promised to extend to the remotest parts of the world, but the ancient Roman contributed but little to science, and we are told by the historian that "a pestilence raged for fifteen years (251-265) and carried off one-half of the inhabitants of the Empire." The seat of civilization was moved to the shore of the Bosphorus, but the lamp of science was well-nigh extinguished and the clouds of the middle ages enveloped the world and shrouded its inhabitants for more than a thousand years. "A fabulous and formless darkness overcame the fairest things of earth."

If one reads the history of the decline of the Roman Empire, he can hardly fail to see that disease was an important factor in that retrograde movement, which involved the greater part of the then known world. Jones and Ross find the earliest reference to malaria among the Romans in the comedian Plautus, who died 184 B. C., and they quote Terence, who died 159 B. C., and whose language is explicit in showing not only the prevalence of malaria, but also the recognition of the different forms. From that time on, reference to the wide prevalence of malarial diseases, not only in the open country, but also in the city, is frequent and definite. Jones says:

> There is then, every reason for supposing that malaria was unknown in Italy in early times, was well known at the beginning of the second cenutry B. C., and that it gradually became more common during the next two hundred years. If this be so, it is at least a plausible conjecture that it was introduced by Hannibal's Carthaginian mercenaries. Africa seems to have been the original home of the disease, and it is probable that some of his troops were infected. The constantly repeated devastation of Italy in the second Punic war would be sure to turn a large part of it into marshy land, thus affording a convenient breeding-place to the mosquitoes which were infected by the malarial patients among the Carthaginians. The similar conditions of Attica during the closing years of the fifth century B. C. offers a striking parallel. This opinion does not rest on mere conjecture. We are told by Livy that in the year 208 B. C. a severe epidemic attacked Italy. It did not cause many deaths, but resulted in much lingering disease, that is, most probably, chronic malaria.

Malaria, however, was not the only disease which contributed to the degeneration of the Roman people. I have already referred to the pestilence of the third century, which is said to have destroyed half the inhabitants of the vast empire within fifteen years. This certainly was not malaria. Moreover, this was not the first great pestilence which afflicted the Roman Empire. Neuburger says:

> The "plague," so called by Galen or Antonine, was first introduced from Syria by the Roman army. . . . The extraordinary contagiousness of the epidemic is emphasized in all contemporary reports. There appear to have been a variety of simultaneous manifestations, the descriptions indicating afflictions chiefly resembling small-pox, or dysentery, but adequate criteria on which to express an opinion are wanting. The "plague" commenced 165 A. D., claimed innumerable victims and lasted at least fifteen years.
>
> Jerome writes: With peace, order and good government a curious lethargy fell on the warrior state deepening into a coma in which it died so quietly that neither the contemporaries nor we moderns can fix the date of the decease. The fact, however, finally became apparent when the phenomena of decay were indubitable and the world, deprived of the master, fell back helplessly into a condition hardly more advanced than in the ages before its subjection, save that it had the imperishable memory of Rome to give it hope, direction and courage.

In the fourth century the seat of government was removed to Byzantium. It is probable that this change was, in part at least, determined by the insalubrity of Italy. Early in the fifth century Rome was pillaged, but the real conquerors of Rome were not the Goths and Vandals, but malaria and the plague. Disease continued to devastate Italy. Creighton says:

> About the year 668 the English archbishop-elect, Vighard, having come to Rome to get his election confirmed by the pope, Vitalanius, was soon after his arrival cut off by the pestilence with almost all who had gone with him. Twelve years after, in 680, there was another severe pestilence in the months of July, August and September, causing a great mortality at Rome and such a panic at Pavia that the inhabitants fled to the mountains. In 746 a pestilence is said to have advanced from Sicily and Calabria and to have made such devastation in Rome that there were houses without a single inhabitant left.

From that time on the plague periodically spread over Italy until the seventeenth century, while malaria has been in continuous possession down to our own time. We are told that the epidemic of 1348 reduced the inhabitants of the Eternal City to 20,000.

We are familiar with the graphic description of the plague in Florence by Bocaccio, who wrote:

> Such was the cruelty of Heaven, and perhaps of men, that between March and July following, it is supposed, and made pretty certain, that upwards of a hundred thousand souls perished in the city only, whereas, before that calamity, it was not supposed to have contained so many inhabitants. What magnificent dwellings, what noble palaces were then depopulated to the last person, what families extinct, what riches and vast possessions left, and no known heir to inherit, what numbers of both sexes in the prime and vigor of youth — whom in the morning neither Galen, Hippocrates nor Esculapius himself, but would have declared in perfect health — after dining heartily with their friends here, have supped with their departed friends in the other world.

There are but few passages in literature so tragic as the short record of the plague of the fourteenth century begun by the friar of Kilkenny, but soon interrupted by his death:

> I friar, John Clyn, of the order of Friars Minor and of the convent of Kilkenny, wrote in this book those notable things which happened in my times, which I saw with my eyes, or which I learned from persons worthy of credit. And lest these things worthy of remembrance should perish with time and fall away from the memory of those who are to come after us, I, seeing these many evils, and the whole world lying, as it were in the wicked one, *among the dead, awaiting death*—as I have truly heard and examined, so have I reduced these things to writing; and lest the writing should perish with the writer, and the work fail altogether with the workman, I leave parchment for continuing the work, if haply, any man survive, and any of the race of Adam escape this pestilence and continue the work I have commenced.

That the period of the Byzantine Empire (395-1453) was one of general degeneracy is shown on every page of the historian. It produced no literature of merit, and "the study of nature was regarded as the surest symptoms of an unbelieving mind." Neuburger says:

> The Byzantines merely followed the downward path. Surfeited with tradition, which made modes of thought appear inevitable, because customary, filled as a nation with overweening self-conceit, fed by the glories of the Graeco-Roman past, they neither could nor would destroy the historic bridge nor replace the crumbling ruin with a new edifice. It lay outside the sphere of their interests to enter into that conscious emulation of antiquity which, emphasizing the growing contrast between past and present, and eliminating the obsolete and the inert, is the essence of mental cultivation. Forgetting that it was the free development of the national spirit which constituted the greatness of the past, they went so far as to smother its liveliest expression by denying, in their rigid adherence to Attic speech, all part in literature to the language of the people. The more incapable did the Byzantines become of grasping the spirit, the more tenaciously did they cling to the letter — a reflection of the mania for titles and ceremonies in political life — and thus they dragged the inanimate mechanism, the dry bones of antiquity through a thousand years, instead of erecting a new edifice on the foundations of antiquity.

The physician and historian, Procopius, in his account of the great pestilence in the reign of Justinian "emulated the skill and diligence of Thucydides in the description of the plague at Athens." Of this epidemic Gibbon says:

> In time its first malignancy was abated and dispersed; the disease alternately languished and revived; but it was not till the end of a calamitous period of fifty-two years, that mankind recovered their health, and the air resumed its pure and salubrious quality. No facts have been preserved to sustain an account, or even a conjecture, of the numbers that perished in this extraordinary mortality. I only find that during three months, four and at length ten thousand persons died each day at Constantinople, that many cities of the east were left vacant, and that in several districts of Italy, the harvest and the vintage withered on the ground. The triple scourge of war, pestilence and famine afflicted the subjects of Justinian, and his reign is disgraced by a visible decrease of the human species, which has never been replaced in some of the fairest countries of the globe.

This epidemic spread over the whole of Europe and it took more than a century to reach England, where "it fabled long after in prose and verse as the great plague of Cadwalladers time." Then for quite a thousand years it reaped its periodic harvests as often as immunity was lost in new generations.

The historian, as a rule, confines his descriptions to martial and political events and consequently gives a wholly erroneous idea of true conditions. Gibbon says: "If a man were called upon to fix the period in the history of the world, during which the condition of the human race was most happy and prosperous, he would without hesitation, name that which elapsed from the death of Domitian to the accession of Commodus" (from 96 to 180 A. D.). Noah Webster, in his work on epidemics and pestilence, quotes the preceding with the following just comment:

> It is certain that, at this time, the Roman Empire was in its glory, and governed by a series of able and virtuous princes, who made the happiness of their subjects their principal object. But the coloring given to the happiness of this period is far too brilliant. The success of armies and the extent of empire do not constitute exclusively the happiness of nations; and no historian has a title to the character of fidelity, who does not comprehend, in his general description of the state of mankind, moral and physical, as well as political evils.

Let us make brief inquiry into the diseases of this "most happy and prosperous" period. It was preceded by, it begun in, continued in, and closed in pestilence. That the plague was endemic in Italy at that time and that it developed in epidemic form with each increase in susceptible material there can be no doubt. Of the epidemic of 68 A. D. Tacitus says:

> Houses were filled with dead bodies and the streets with funerals; neither age nor sex were exempt; slaves and plebeians were suddenly taken off, amidst the lamentations of their wives and children, who, while they assisted the sick, or mourned the dead, were seized with the disease, and perishing, were burned on the same funeral pyre. To the knights and senators the disease was less mortal, though these also suffered in the common calamity.

About this time the plague appears to have spread over the whole of Asia, northern Africa and Europe. According to Short, the deaths from this disease in Scotland between 88 and 92 A. D. amounted to not less than 150,000. This was probably not less than one-fourth, possibly one-half, the population of Scotland at that time.

In the year 80 A. D. the deaths from the plague in Rome at the height of the epidemic numbered 10,000 a day. It is estimated that the population of Rome at that time was somewhat more than one million. Exacerbations of the disease in Rome are recorded for the years 102, 107 and 117 A. D. According to Short, 45,000 died of the plague in Wales in 114. The year 167 A. D. is noted for an unusually severe outbreak of the plague at Rome, where it continued for many years. In the year 173 A. D., the Roman army was threatened with extinction by disease, and special epidemics, or rather exacerbations of the epidemic, prevailed in Rome in 175 and 178 A. D. That the "happy and prosperous" period was followed by a continuation of the plague is shown by the following quotation from Herodian:

> A great pestilence raged throughout Italy at that time (about 187 A. D.), but with most violence in the city, by reason of the great concourse of people assembled from all parts of the earth. The mortality among men and cattle was great. The Emperor, by advice of physicians, retired to Laurentium, on account of the coolness of the place, which was shaded with laurels. It was supposed that the fragrance of the laurels acted as an antidote against the contagion. The people in the city also, by the advice of physicians, filled their noses and ears with sweet ointments and used perfumes, etc.

Under the spell of the historian we have been inclined to regard the period when the greater philosopher, Marcus Aurelius Antoninus, sat on the throne of the world, as the golden age. Let us therefore listen to a few words from his personal attendant, courtier and historian, who writes:

> Unless he, M. Antoninus, had been born at this juncture, the affairs of the empire would have fallen into speedy ruin; for there was no respite from military operations. War raged in the east, in Illyricum, in Italy and in Gaul. Earthquakes with the destruction of cities, inundations of rivers, frequent plagues, a species of locusts ravaging the fields; in short every calamity that can be conceived to afflict and torment man scourged the human race during his administration.

It is estimated that during the dark ages the average of human life was less than twenty years. A high birth-rate was necessary to keep the race alive, but notwithstanding this, Europe was sparsely inhabited. At the time of the Norman Conquest the inhabitants of England numbered between two and two and one-half million, probably nearer the former, for they had not reached the greater number a hundred years later. Creighton says: "It would be within the mark to say that less than one-tenth of the population was urban in any distinctive sense of the term. After London, Norwick, York and Lincoln, there were probably no towns with five thousand inhabitants." Indeed, urban life, as we now know it, was quite impossible in this age of pestilence and would soon become so again were the functions of preventive medicine relaxed.

Most of the great epidemics of the middle ages were designated as *pestilentia or magna mortalitas*. In the most deadly visitations the bubonic plague is so accurately described that there can be no doubt about its identity, but it must not be supposed that the people enjoyed any high degree of health even in those periods when this contagion languished on account of exhaustion of susceptible victims. Ergotism, under the name of Saint Anthony's fire, was endemic in France and adjacent territories; Normandy was filled with lepers, but Christ's poor were not confined to that country. England was regarded as the special home of hunger, but abundance was a stranger to the masses in every land. The mysterious sweating sickness, apparently brought to England with Henry Tudor in 1485, developed in five distinct epidemics which were characterized by the fact that the mortality was greater among the rich than the poor. Typhus, known as *morbus pauperum*, prevailed largely in the jails, on ships and among the squalid inhabitants of the cities. Even the discovery of America carried to Europe the scourge of syphilis, which was spread over Italy by the soldiers of Charles VIII, and within a few years reached the most distant parts of Europe. Small-pox appeared in England in the sixteenth century, having journeyed, according to the most reliable authority, all the way from the Orient. That tuberculosis, diphtheria, dysentery and other diseases, still with us, prevailed during the middle ages is shown by the records, but they were overshadowed by the higher mortality of those mentioned above. Improved agriculture has extinguished the fire of St. Anthony, except in the most benighted provinces of Russia. The great fire in London in 1666 destroyed the infected rats and relieved England of the bubonic plague, which had been endemic in that country since 1349. Something more than one hundred years later the discovery of Jenner robbed small-pox of its horrors, wherever vaccination is properly enforced. The investigations of Howard improved the sanitation of jails and workhouses, and did much to eradicate typhus.

The claim has been advanced that the infectious diseases have benefited the race by the destruction of the unfit. This idea I have combated most vigorously since our study of typhoid fever in the Army in 1898. My colleagues and I found that out of 9,481 soldiers who had previously been on the sick report and could not be regarded as possessing standard health, 648, or 6.8 per cent., contracted typhoid fever; whereas, out of 46,384 men who had no preceding illness, 7,197, or 15.3 per cent., developed typhoid fever. More than 90 per cent. of the men who developed typhoid had no preceding intestinal disorder. Under ordinary conditions the strong, busy man, especially the one whose activities demand wide excursions from his home, is more likely to become infected than the one whose sphere of action is more limited on account of infirmity. The reason for this is too obvious to need statement, and it follows that more men than women and more adults than children have typhoid fever. Moreover, the case mortality is greater among the strong, because death in the infectious diseases is often due to the rapidity with which the invading organism is broken up by the secretions of the body cells and the protein poison made effective. From this I have concluded that contagion, like war, destroys the very flower of the race. This view is sustained by the historians of the pestilences of former times.

Thucydides in his description of the plague at Athens says: "Moreover, no constitution, whether in respect of strength or weakness, was found able to cope with it; nay, it swept away all alike, even those attended to with the most careful management."

Procopius in his account of the Justinian epidemic states that youth was the most perilous season, and females less susceptible than males.

Cogan, in describing the outbreak of typhus at Oxford in 1577, writes: "The same kind of ague raged in a manner over all England, and took away very many of the strongest sort, and in their lustiest age, and for the most part, men and not women and children, culling them out here and there, even as you would choose the best sheep out of a flock."

In his account of the plague of 1665 in London, Boghurst makes the following statement: "Of all the common hackney prostitutes of Luteners-lane, dog-yard, cross-lane, Baldwins-gardens, Hatton-gardens and other places, the common criers of oranges, oysters, fruits, etc., all the impudent drunken, drubbing bayles and fellows and many others of the *rouge route*, there is but few missing — verifying the testimony of Diemerbroech that the plague left the rotten bodies and took the sound." Like testimony comes from an account of the plague at Moscow: "Drunkards and persons of feeble temperament were less subject to attack."

Davidson observed that typhus fever was more frequent among the robust than the weak. He states that out of 429 cases the spare and unhealthy taken together made only about 17 per cent. He adds that the death-rate among the poor was one in twenty-three, while among the well-to-do it was one in four. The greater mortality of typhus among the higher classes has been noted by Barber and Cheyne and by Braken.

Hurty, nearly a century ago, wrote: "A fever which consigns thousands to the grave, consigns tens of thousands to a worse fate — to hopeless poverty, for fever spares the children and cuts off the parents, leaving the wretched offspring to fill the future ranks of prostitution, mendicancy and crime."

Creighton says:

> The best illustrations of the greater severity and fatality of typhus among the well-to-do come from Ireland in times of famine, and will be found in another chapter. But it may be said here, so that this point in the natural history of typhus may not be suspected of exaggeration, that the enormously greater fatality of typhus (of course, in a smaller number of cases) among the richer classes of the Irish families, who had exposed themselves in the work of administration, of justice, or of charity, rests on the unimpeachable authority of such men as Graves, and on the concurrent evidence of many.

A surgeon in the British navy at the time of William III and Anne tells how he was led to practice bleeding in fever as follows:

> I had observed on a ship of war, whose complement was near 500, in a Mediterranean voyage in the year 1694, when we lost about 90 or 100 men, mostly by fever, that those who died were commonly the young, but almost always the strongest, lustiest, handsomest persons, and that two or three escaped by such natural hemorrhages, which were five or six pounds of blood.

The middle ages were indeed dark physically, intellectually and morally. Here and there, now and then, some man of genius towered above the general low level of his contemporaries and not infrequently he paid dearly for his audacity. For some centuries the Arab, especially in Spain, stood out alone as the torch-bearer of science, and he, when driven back into the insalubrity of Northern Africa, lapsed into barbarism. Neuburger writes:

> Fortunately the fate of medieval medicine was not dependent on Byzantium alone. An admirable illustration of the doctrine of conservation of energy is afforded by the fact that, with the decline of intellectual energy at home, a contemporaneous development of Greek medicine took place abroad, which, if at times misguided, was yet full of vitality, whilst the medical art of the newly arisen world of Islam reached a height unsurpassed during the middle ages.

In the greater part of Europe, ignorance and disease held full sway. In the midst of great calamities "the will-o-the-wisp of superstition is an irresistible attraction and offers the only ray of hope." Strong men, neglectful of their earthly duties, betook themselves to secluded places and lost themselves in dreams of a heavenly paradise. Mysticism, fanaticism and superstition dominated all conditions of men. Rulers, illiterate, immoral and even incestuous, occupied palaces while the masses died of starvation. The history of the time is a record of diseased, degenerated, demented man. There can be no doubt that disease has overthrown civilizations in the past, and there is no surety that it may not do so again. The recent outbreak of the plague in Manchuria and its more recent appearance in Cuba are not without their warnings. It remains to be seen if those who control our government have the intelligence necessary to protect our country against the invasion of pestilence. The failure to provide for camp sanitation in 1898, the behavior of California officials on the finding of plague in San Francisco and the general indifference of national and state authorities toward the eradication of disease discourage the hope that intelligent patriotism is widely distributed among us. As a contemporary of Mr. Dowie and Mrs. Eddy and as a citizen of a country in which the osteopath and chiropractic flourish, I feel some embarrassment in speaking of the fanaticism and ignorance of the dark ages.

The history of medicine is that of mankind. Born in naked ignorance, bound in the swaddling-clothes of credulity and nursed on superstition, medicine has had its savants and its fakers, its triumphs and its failures, its honors and its disgraces. It has attracted and still attracts to its ranks men of the purest motives and those who are impelled by the basest desires. It can be said without fear of contradiction that medicine has done more for the growth of science than any other profession, and its best representatives in all ages have been among the leaders in the advancement of knowledge, but the average medical man conforms in intellect and character to the community in which he lives. The food of the faker is ignorance and he thrives where this commodity is most abundant. The uncontrolled fool moves to his own destruction. This is the only way in which Nature can eliminate him. A wise government protects its incompetents from medical and other fakers, but such government can exist only where wisdom predominates.

A study of epidemics shows that in the presence of wide-spread contagion mankind in the mass tends to revert to the barbaric state. This is the unvarying testimony of all authorities, medical and lay, secular and religious, who have made the records. The historian Niebuhr, in discussing the report on the plague in Athens by Thucydides says: "Almost all great epochs of moral degradation are connected with great epidemics." F. A. Gasquet, abbot president of the English Benedictines, in his history of the black death, writes: "The immediate effect on the people was a religious paralysis. Instead of turning men to God, the scourge turned them to despair, and this not only in England, but in all parts of Europe. Writers of every nation describe the same dissoluteness of manners consequent upon the epidemic." A Venetian historian notes the general dissoluteness which followed the disease and its effects in lowering the standard of probity and morals. Covino of Montpellier bears testimony to the baneful effects of the scourge on the morals of those who escaped, and concludes that such visitations exercise the most harmful influence on the general virtue of the world. William of Nangis, in his history of the plague in France in 1348, con . . with the following:

> But alas! the world by this renovation is not changed for the better. For people were afterwards more avaricious and grasping, even when they possessed more of this world's goods than before. They were more covetous, vexing themselves by contradictions, quarrels, strifes and lawsuits.

Many similar references could be given, but these suffice to show that disease breeds ignorance, immorality and strife. Our inquiries into the influence of disease on civilization, however, have brought out the fact that people living in comparative health have within a few generations made beginnings, at least, some, highly creditable, in government, literature and science. The Hellenic tribes of Greece built up their wondrous civilization within a few centuries. It is true that Rome was not built in a day, but the seven hills were covered with houses and temples, the great aqueducts brought abundant supplies of pure water from the mountains and the wonderful sewers remain as evidence of sanitary skill, and all this was accomplished in a relatively short period measured in the history of the race. The world moved forward at a rapid pace with the dawn of science in the last century. It is not extravagant to prophesy that with ten centuries of freedom from disease, both inherited and acquired, the world would be regenerated and the superman be born.

It is not necessary to turn to history for examples of the degrading effects of disease on man. We see it to-day in the physical inferiority, intellectual weakness and moral irresponsibility of those peoples who are still under the domination of malaria and kindred diseases. My illustrious predecessor in this office, Dr. Gorgas, has demonstrated what scientific medicine may accomplish in these pestilential regions, and it is within reason to look forward to the time when the tropics may supply choice locations for civilized man. In like manner the valleys of the Tigris and Euphrates are being reclaimed and Babylon and Nineveh may again become seats of learning and culture. The modern sanitarian is quite competent to rebuild the home in which the cradle of civilization was rocked.

After the last epidemic of the plague in London in 1665 the death-rate, so far as it can be ascertained, fell to between 70 and 80 per 1,000. During the next century it fell as low as 50, but fluctuated greatly with recurring epidemics of typhus and small-pox. In the nineteenth, it gradually and quite constantly decreased and is now about 14. In 1879-80, the first year in which the mortality statistics of the United States possess sufficient accuracy to be of any value, the death-rate in the registered area was 19.8; in 1912 it was 13.9 — a decrease of 30 per cent. During the same time the mortality from typhoid fever has decreased 50 per cent.; that from scarlet fever 89 per cent.; that from diphtheria 84 per cent.; that from tuberculosis 54 per cent Hoffman states that had the death-rate for tuberculosis in 1901 continued there would have been 200,000 more deaths from this cause from that date to 1911 than actually did occur, or the actual saving of lives from death by tuberculosis accomplished in that decennium averaged 20,000 per year. A battle in which 20,000 are slain stirs the world at the time and fills pages of history later. Preventive medicine measures its successes by the number of lives saved, and 20,000 a year preserved from death from one disease is no small triumph. In the last century the average of human life has been increased fifteen years and this increase could be duplicated in the next twenty years if the facts we now possess were effectively employed.

Hoffman further states that the addition to the material wealth of this country secured by the reduction of deaths from tuberculosis within ten years amounts approximately to 6,200,000 years of human life, covering its most productive period. Medicine discovered the facts which have made this great work possible and has directed their application. With evidence of this kind before them, will our lawmakers listen to those who demand recognition as practitioners of medicine without proper qualification?

The further developments of medicine, both curative and preventive, depend on scientific investigations. The public is the beneficiary and should in every way encourage medical research. By the application of discoveries already made, the burden of disease has been lightened, sickness has become less frequent and less prolonged, a greater degree of health has been secured, the efficiency of the individual and of the nation has been increased and life has been prolonged and made more enjoyable. The federal government and the states should sustain and promote scientific research. That government is the best which secures for its citizens the greatest freedom from disease, the highest degree of health and the longest life, and that people which most fully secures the enjoyment of these blessings will dominate the world.

Medicine consists of the application of scientific discovery to the prevention and cure of disease. All else which may go under the name of medicine is sham and fraud. Without advancement in the physical, chemical and biologic sciences there can be no progressive movement in medicine. Scientific knowledge is gained only by observation and experiment. Before the time of Jenner, we are told by the historian, it was unusual to meet in London one whose face was not marked by small-pox. There was a popular belief that one who had cow-pox was immune to small-pox. Jenner put this belief to a scientific test and the result was the discovery of vaccination, and this secured the abolition of this disfigurement and a marked reduction in mortality.

In 1849, a village doctor, with a crude microscope, studied the blood of animals sick with anthrax and compared it with that of healthy ones. He discovered the anthrax bacillus. This work was extended by Davaine, Pasteur, Koch and others, and from this the science of bacteriology has been developed. The particulate causes of many infectious diseases have been recognized, isolated and their effects on animals demonstrated. Many of the mysteries of contagion have been revealed and the conditions of the transmission of disease made known. The fundamental principles of preventive medicine have been developed into a science which is to-day the most potent factor in the progress of civilization.

Finlay suspected a certain mosquito to be the carrier of the virus of yellow fever. Reed and his co-workers demonstrated the truth of this theory and the work of Gorgas has freed Havana from the pestilence and the construction of the Panama Canal is an accomplished fact.

We are sorry for the Greek, whose bodily health, mental strength and moral sense were depressed by the invisible and insidious organisms of malaria, and truly his memory deserves our sympathy. He had no microscope, and how could he detect or even suspect that the mosquitoes which had annoyed his ancestors for generations had armed their lancets with deadly poison brought from Africa? The Greek had never heard of quinin and the other cinchona alkaloids. He did not know the land whose forests were even then elaborating those products, which, centuries later, were of greater value than gold to man, and proved to be an essential help in the uplift of mankind. Laveran discovered the *Plasmodium malariae.* Ross studied its life history and the fetters of this disease, which has so long retarded the progress of man, have been broken. Mitchell and Reichart investigated the poisonous properties of snake venon. Sewall immunized animals with it. Ehrlich studied the similar bodies, abrin, ricin and diphtheria toxin, and von Behring and Roux gave the world antitoxin, the magical curative value of which has greatly reduced the mortality from this disease. The experiments of Villemin demonstrated the contagious nature of tuberculosis, long suspected and frequently denied. The diligent research of Koch resulted in the [illegible] and isolation of the causative agent, and [illegible] the mortality of the Great White Plague in Europe and the United States has been diminished more than half, and it is within the range of sanity to look forward to the time, when the former "Captain of the hosts of death" will be known only by the fearful records he once made in the history of man's struggle to be relieved from the heavy tribute paid to infection.

We boast of a great civilization, but this is justified only within limits. Science more nearly dominates the world than at any time in the past. Learning permeates the masses more deeply, but credulity and ignorance are widely prevalent. In this country of nearly one hundred millions, there are thousands whose greed impedes the progress of the whole, tens of thousands whose ignorance retards their own growth, and other thousands who live by crime and procreate their kind to feed on generations to come. We have our schools, colleges and universities, while our almshouses, insane asylums and penal institutions are full. In our cities we see the palatial homes of the ultra rich, the splendid temples of trade and commerce, the slums of want and poverty and the homes, both rich and squalid, of vice and crime. No nation in this condition can be given a clean bill of health. Our hill-tops are illuminated by the light of knowledge, but our valleys are covered by the clouds of ignorance. We have not emerged from the shadows of the dark ages. The historian of the future will have no difficulty in convincing his readers that those who lived at the beginning of the twentieth century were but slightly removed from barbarism, as he will tell that the school, saloon and house of prostitution flourished in close proximity; that the capitalist worked his employees under conditions which precluded soundness of body; that the labor union man dynamited buildings; that whilst we sent missionaries to convert the Moslem and the Buddhist ten thousand murders were committed annually in our midst, and that a large percentage of our mortality was due to preventable disease.

Evidently there is much to be done before we pass out from the shadows of ignorance into the full light of knowledge. In this great work for the betterment of the race the medical profession has important duties to perform. I do not mean to imply that the uplift of mankind devolves wholly on the medical man. The burdens are too many and too diversified, the ascent too steep and the pathways too rough for one profession to hope to reach unaided the high plateau we seek. Moreover, other callings have no right, and should have no desire, to shirk the moral responsibilities, which rest alike on all. But in past ages, medical men have been the chief torch-bearers of science, the only light in which man can safely walk, and we must keep and transmit to our successors this trust and honor. I know of no scientific discovery, from the ignition of wood by friction to the demonstration of the causes of infection and the restriction of disease, which has not sooner or later assisted in the betterment of the race. It may be added that nothing else has so aided man in his slow and halting progress from the pestilential marshes of ignorance to the open uplands of intelligence.

In so great a work as the eradication of preventable disease, all intelligent people must cooperate. The law must support by proper enactments, and these must be enforced with justice and intelligence; it must recognize that the right to enjoy health is quite as sacred as that to possess property; that to poison men in factories and mines, to pollute drinking water-supplies, to adulterate foods and to drug with nostrums is manslaughter. Religion must teach the sanctity of the body as well as that of the soul, that ignorance is sin and knowledge virtue, that parenthood is the holiest function performed by man and that to transmit disease is an unpardonable sin. The teacher must know hygiene as well as mathematics. The capitalist must recognize that improvement in health and growth in intelligence increase the efficiency of labor. There never has been a time when scientific medicine has had so many and such efficient and appreciative helpers as it has to-day. Our sanitary laws are for the most part good, but their administration is weak, on account of ignorance. The pulpits of the land are open, for the most part, to the sanitarian. The respectable newspapers are most effective in the crusade against quackery and disease. The philanthropist has learned that the advancement of science confers the greatest and most lasting benefits on man.

There is a moral obligation to be intelligent. Ignorance is a vice and when it results in injury to any one it becomes a crime, a moral, if not a statutory one. To infect another with disease, either directly or indirectly, as a result of ignorance, is an immoral act. The purpose of government is to protect its citizens, and a government which fails to shelter its citizens against infection is neither intelligent nor moral. To transmit disease of body or mind to offspring is an unpardonable sin. In a reasonable sense it is worse than murder, because it projects suffering into the future indefinitely.

That medicine has become a fundamental social service must be evident. To return one incapacitated by illness or injury to the condition of self-support benefits not only the individual, but the community, inasmuch as it increases its productive capacity. Infirmity is a direct burden on the individual and scarcely less direct on the community. Weakness in any part diminishes the strength of the whole. It is a fully established principle in social economy that widespread intelligence and growth in knowledge are beneficial to the state.

It was in full recognition of this that the framers of the Ordinance of 1787 wrote into that immortal document: "Religion, morality and knowledge being necessary to good government and the happiness of mankind, schools and the means of education shall forever be encouraged." The Territory of the Northwest, the government of which was provided in this ordinance, was at that time a vast waste of forest and prairie, furnishing a scant and precarious subsistence for savage tribes and attracting to its borders a few of the most hardy sons of civilization. The knowledge for whose growth and diffusion the wise provision was made, has drained the malarial marshes, converted wild prairie and tangled wood into fruitful orchards and fertile fields, dotted the whole area with neat villages, reared great cities, linked all parts with steam and electric roads, and provided comfortable homes and abundant food for millions. The men who wrote the Ordinance of 1787 left a great inheritance which is temporarily in our possession. Let us write into this great document: "Every ill which can be relieved shall be removed, and every preventable disease shall be prevented." The wisdom of our fathers has secured for us a greater measure of health and a longer term of life; let us do as well for those who are to possess this fair land in the next generation. Let us live not only for ourselves and the present, but for the greater and more intelligent life of the future.

Not myself, but the truth that in life I have spoken
Not myself, but the seed that in life I have sown
Shall pass into ages — all about me forgotten,
Save the truth I have spoken, the things I have done.

All things are relative and health is no exception. With a greater degree of health among all, religion will become more effective for good, morality will have a deeper significance and a wider application and knowledge will multiply and distribute its blessings more widely.

In the further improvement of the physical, mental and moral conditions of the race, medicine should continue to be a leader. There is no other calling so essential to this movement, and in order to more thoroughly fit itself for this important task the profession should first of all look to its own betterment. The medical man should possess intelligence of high order, manifest industry without stint and show the highest integrity in all he does. That it is the aim of this Association to attract to its colors men possessing these qualifications and to deny admission to others is shown by the advance in the standard of medical education, the enforcement of medical registration laws and the denunciation of every form of medical charlatanism. In all these directions the profession has the support of the more intelligent men in other callings. The improvement in medical training secured within recent years in this country is without a parallel in the history of education. The requirements for admission to the medical schools have been rapidly advanced and standardized; the number of medical schools has been reduced from 166 to 104 by obliteration and combination, much to the improvement of all, and a far better class of matriculates has been secured. The courses of instruction have been lengthened and made more scientific. Each good medical school is doing more or less of research which is not confined to laboratory investigators, but is fast finding its way into hospitals. Indeed, some of our clinical men are now making most valuable contributions. Every medical man should have much of the spirit of research. It is the pabulum on which medicine feeds and without it the profession atrophies and starves. It is the glory and strength of the profession that it is not bound by dogma and pays no heed to ipse dixits. I have no sympathy with the idea that medical research should be largely relegated to special non-teaching institutions. These have their function and we rejoice in their foundation and support and hope that they may multiply, but the man who is devoid of the spirit of scientific investigation has no place in medicine as student, practitioner or teacher, and the most elaborate medical training without opportunity for scientific observation is barren. Besides, opportunities for medical discovery should be widely distributed. Science makes no provision for an aristocracy. There can be no papal bulls issued in the domain of medicine. The workers must be many, all must be free to pursue knowledge in their own way, and all must be compelled to prove their claims, for "life is short, art is long, opportunity is fleeting, experiment fallacious and judgment difficult."

In this work of self-improvement the profession has had the aid of the more intelligent law makers and administrators. In carrying out these progressive changes there has been much sacrifice of money and personal pride by many members of the profession. Large schools have willingly submitted to marked reduction in the numbers of their students and consequently in financial support. A medical education costs more in time and money than that demanded by any other profession, and the emoluments of the average practitioner have decreased as preventive medicine has become more effective. No other profession pays so heavily the great cost of eradicating the infectious diseases, but this is the function of medicine and no sacrifice should be regarded as too great. While intelligent medical men have been leading the crusade against greed, ignorance and disease, our legislative halls have been crowded with the representatives of sects, cults and charlatans demanding legal recognition. If I mistake not, herculean efforts will be made in the near future to lower the standards demanded of the medical practitioner. These endeavors have been promised aid from those who have heavy financial backing, but if we are worthy of the trust which we bear, we will not yield. We must appeal to the good sense of the people for whose welfare we labor. We must show what scientific medicine has done for the public good and point out the greater things it may do with increased opportunity. It must be admitted that in the crusade for the restriction of tuberculosis many physicians have manifested but little interest. This is shown by their slowness to employ methods of early diagnosis and consequently by their failure to recognize the disease in its curable stage, also by their unwillingness to comply with the laws of notification. It is an undeniable fact that there are many medical men who know less about hygienic measures than the more intelligent of the laity. With advancing knowledge among the masses these professional fossils will be correctly labeled and properly shelved in the local museums of antiquities.

I believe that medicine is now attracting excellent young men. It should appeal to this class. It does not point the way to great financial reward, but it offers a service unsurpassed by any other calling. The historian tells us: "For the Roman patriot the only worthy stage was the forum or the battlefield; every other pursuit was left in the hands of slaves and could not free itself from the taint of servitude." Modern medicine offers a field in which the advancement of knowledge, the improvement of health conditions and the saving of lives are the measures of success.

Preventive medicine, still in its youth, has accomplished great things. As I have stated, within the past thirty years in this country the mortality from tuberculosis has been reduced more than half and with scarlet fever and diphtheria the results have been more striking. Within the past ten years the average life has been increased four years. Great epidemics which once devastated continents are no longer known in the more intelligent parts of the world. In fact, it may be said that the death-rate is now an excellent measure of intelligence. In 1911 the death-rate in London was 15 per one thousand, while that of Moscow was 27.3. Preventive medicine is the keystone of the triumphal arch of modern civilization, and its displacement would precipitate mankind into relative barbarism. Should the health administrators of any great commercial center fail, for even a few months, to exercise the function of restricting disease, the history of the epidemics of the middle ages might be repeated. Great things have been done, but greater tasks lie before us, and their accomplishment depends on the scientific wisdom of our profession and the intelligence of the people. Without the harmonious adjustment of these forces the greatest efficiency cannot be secured. While the mortality from tuberculosis has been reduced half in the past thirty years, we must not assume that the total eradication of this disease will be accomplished in the same number of years. Only the more progressive members of the profession have taken the initiative, and only the more intelligent members of the community have responded. Intelligence and the sense of moral responsibility must grow as the work proceeds. It remains for all who have the welfare of the race at heart to plan wisely and carry forward courageously the campaign against greed, ignorance and disease.

The sanitarians of this country seem to be in harmony in regard to the general procedures to be followed. These are embodied in bills recently introduced in the legislative assemblies of a number of states. In New York an excellent bill was passed and its operation is now being inaugurated under the directorship of Dr. Biggs, whose long and effective service in the city of New York demonstrates the wisdom of his selection. I regard it as highly fortunate that the operation of this new and important law is to be directed by one so well qualified.

My own ideas are embodied in the "Amberson bill" of the Michigan legislature of 1913. Among the provisions of this bill the following may be mentioned: The state is to be divided into health districts. In each such district a health commissioner is to be appointed for a term of four years. The fitness of the commissioner is to be determined by the State Board of Health after examination. The salary of the commissioner varies with the population of the district, but in most instances would run from three to six thousand dollars. There is to be an additional appropriation for laboratory expenses and for carrying out the purposes of the act.

> It shall be the duty of the health commissioners to be vigilant in the work of disease prevention and the conservation of the public health, and to enforce all health laws of the state and health ordinances of their respective localities, together with all rules and orders of the state board of health; to collect and report to the state board of health morbidity statistics and to make a monthly report of the work done by them in narrative form to the state board of health and in such tabular form as may be prescribed by the state board of health. Copies of such reports shall be retained by each commissioner in permanent record books. They shall make such sanitary inspections and surveys of the district as may be required from time to time by the state board of health or by the city for which appointed, or by resolution of the board of supervisors of each county. They are hereby authorized and invested with the power to enter on and inspect private property at proper times in regard to the possible presence, sources or cause of disease, to establish quarantine and in connection therewith to order whatever is reasonable and necessary for the prevention and suppression of diseases; to close schools, churches, theaters, or any place of public assemblage, to forbid public gatherings in order to prevent or stay epidemics; to collect statistics concerning insanity, feeble-mindedness, tuberculosis and other infectious diseases; to inspect slaughter-houses and markets of all kinds where food is sold. They shall inspect at least once each six months and make a sanitary survey of the publicly owned buildings and institutions within their respective jurisdiction and shall keep a report thereon as part of the records of their office. They may inspect any school buildings or grounds within their jurisdiction as to sanitary conditions and shall have power to close any school when the sanitary conditions are such as to endanger or imperil the health or life of the pupils attending the same. They shall include all such sanitary inspections in their monthly reports to the state board of health. They shall at all times be subject to the orders of the state board of health in the execution of the health laws of this state and may perform any duty where required by the state board of health, or any member of said board acting for the entire board, which might be performed by said board of health or an officer thereof.

Further duties of the health commissioners are defined in the bill, and I have given only enough to show the purpose and scope of its provisions.

The successful operation of such a law would require the highest class of sanitarians. They must possess intelligence, industry and integrity. They must be devoted to their work, remembering that the Father of Medicine said: "Where love of mankind is, there also is love of art." With these qualifications I believe that such a law might be operated with great benefit to the people. Is the medical profession of this country prepared to do this work? I believe that many of the recent graduates of our best schools are fitted for this highly important function. They may need special training in the courses in public health now being inaugurated. If I mistake not, our profession will soon have wide opportunity to demonstrate its usefulness in this direction. If the public makes this demand, preventive medicine will have the opportunity to do a patriotic service which has never come to any profession at any time. With proper facilities and helpers, such commissioners might within a few years become acquainted with the conditions surrounding every permanent resident within his jurisdiction, and with properly qualified administrators of the law much might be done to abate disease, improve health, increase efficiency, eradicate the venereal diseases, stamp out vagrancy, pauperism, prostitution, alcoholism and crime. Crime is a disease due to heredity or environment, one or both. We now permit it to breed and multiply in our midst. Its causes must be determined and eliminated and its habitations must be discovered, disinfected or destroyed. We have heard too much about the rights of the individual; let us know more about his duties. Too much stress has been laid on the sacredness of private property and too little on the duty of all to contribute to the welfare of the whole. Preventive medicine has demonstrated in a practical way the force of the biblical statements that no man liveth to himself alone, and that every man is his brother's keeper. Preventive medicine is the most potent factor in the socialistic movement of the day with which every good man feels himself more or less in sympathy; besides it is at the same time the most powerful weapon against the anarchy with which some would threaten us.

If preventive medicine is to bestow on man its richest service, the time must come when every citizen will submit himself to a thorough medical examination once a year or oftener. The benefits which would result from such a service are so evident to medical men that detail is not desirable. When recognized in their early stages most of the diseases which now prevail are amenable to treatment. The early recognition of tuberculosis, cancer, diabetes, nephritis, heart disease, etc., with the elimination of the more acute infectious diseases would add something like fifteen years to the average life, besides saving much in invalidism and suffering. The ultimate goal of science is the domination of the forces of nature and their utilization in promoting the welfare of mankind. Science must discover the facts and medicine must make the application for either cure or prevention.

The local health authorities for which the bills referred to make provision must be supervised by State Boards of Health or State Commissioners. Many of our State Boards of Health are already doing much, but this is little compared with what they might do. They should be absolutely free from party dictation, should be made up of men both qualified and interested and their executive officers should be distinguished for their knowledge of sanitation. Their appropriations should be greatly increased, for health is a purchasable commodity. Pure water, pure food and even pure air cost money, but they lead to health, which is worth more than gold to both the individual and the state.

Our present national health service is doing most excellent work. It demonstrated its strength in eradicating the plague in California and the suppression of yellow fever in New Orleans. It has charge of the administration of the laws affecting the admission of immigrants, so far as their health is concerned, and it performs this service well. The Public Health Service is now investigating the pollution of certain rivers, studying trachoma in the mountains of Kentucky, pellagra in South Carolina and the spread of typhoid fever in certain districts. The Hygienic Laboratory at Washington has made valuable researches in addition to the routine work of the examinations of vaccines and serums. This bureau should be developed into a department with a member in the cabinet. The study of contagion in our midst is quite as important as anything within the range of the activities of the Departments of the Interior, Agriculture and Commerce and Labor. Our health relations with other nations concern us quite as much as our trade relations. The one thing above all others against which our doors should be shut is disease, whether it be of plant, animal or man, whether it be of body, mind or morals. The highest function of the state is not to make millionaires out of a few importers or to find profitable investments for its surplus wealth in foreign lands, but to advance to the highest degree the health, intelligence and morality of its citizens.

In each state there should be a hygienic laboratory equipped with able men supplied with facilities for the study of sanitary conditions and for the prosecution of scientific research. The Hygienic Laboratory at Washington should be developed into a great institution for research which would improve the conditions of life. The greatest asset of any nation is the health of its citizens and the people who secure this in the highest degree will dominate the earth for the dominion of the superman, when he comes, will extend from pole to pole, not by force of arms, but by example and education.

Younger members of the profession: One who is soon to be mustered out of service, on account of disability and old age, salutes you. An old soldier who has served in the ranks nearly forty years, steps from his decimated regiment, lifts his cap and cheers you, as you pass by in your new dress and armed with weapons of greater efficiency than was known when he enlisted. The cause is the liberation of the race from the bonds of superstition and ignorance and it is a glorious one. The contest began before the genus *homo sapiens* came into existence. Countless generations have served their time, some well, some ill, and have passed into oblivion, but their partial victories have made you stronger and placed on you a greater responsibility. Your intelligence is greater, your judgment is sounder and your effectiveness has been increased. Where the past has failed or only partially succeeded, your success will be greater. But the battlements of ignorance still bristle with heavy-fire guns. Only a few of the outposts of the enemy have been captured. It is for you to do and then like all your predecessors to die. You stand to-day within the firing-line. Go on courageously and when eons of the future have become the past, the superman, born out of the struggles of his predecessors, will demolish the last citadel of ignorance and vice, and firmly plant on the highest peak of the mountain of knowledge the flag of human progress and when the silken banner shall unfold, there shall appear on it this legend:

Pro gloria omnium nationum et hominum honore.

AEROPHAGY [*]

CHARLES D. AARON, Sc.D., M.D.
DETROIT

Belching of gas is the most common symptom accompanying gastric disease. We find it present in nearly every organic and functional affection of the digestive tract. The several gastric neuroses always have eructations as their one prominent symptom. These eructated gases were formerly supposed to be the result of fermentation or putrefaction; we now know that in the majority of instances the eructations consist in the main of swallowed air. This is easily understood when we consider what really takes place.

When patients are suffering from a disease of the stomach, the proteins or carbohydrates are apt to decompose, producing some little gas. The pressure induced by this gas is readily relieved by belching. The patient remembers the great relief thus produced, and when he has a similar attack of gastric weight, pressure, distention or pain, his first thought is to get relief by raising the gas from the stomach. An effort is required, and in the effort the patient unconsciously swallows air, allowing it to come back quickly after each expulsive contraction of the stomach, and thus he becomes an aerophagic. The spasmodic swallowing of air, followed by eructations, has been termed "aerophagy," and it accompanies more or less every disease of the alimentary tract. It is seldom found by itself, although there are cases of primary aerophagy.

---

[*] Read before the American Gastro-Enterological Association at Atlantic City, June 21 and 22, 1914.

Neurotic persons are known to have a habit of eating or swallowing air (aerophagy). At one time it was supposed to be pathognomonic of a neurosis, and when a case was encountered the physician would look for other evidence of hysteria or neurasthenia. Aerophagy is present in many neuroses and it is also found as an accompaniment in several gastro-intestinal diseases.

Physiologically, a certain quantity of air is carried into the stomach in the act of eating and drinking and when swallowing saliva. It is only when the quantity becomes excessive that the process assumes pathologic significance. Not infrequently, when large quantities of air are swallowed, a cardiospasm occurs, inducing many disagreeable symptoms, because the air cannot return through the cardia.

The persistent swallowing of gum-chewers leads to aerophagy. This might also occur in patients who are continually swallowing mucus from a retropharyngeal catarrh. In the majority of cases, however, the patient experiences discomfort after meals which he attributes to gas, and in his effort to obtain relief forces air directly into the esophagus so that he may belch. These patients unconsciously become air-swallowers.

Notwithstanding the fact that aerophagy is common, careful study and observation are required for diagnosis. Most patients ridicule the idea that they are air-swallowers, and the physician who would accuse them of it before he is quite sure he can prove it to them would show lack of tact. Many patients, however, who complain of pressure after meals with eructations of gas, are neurotics.

In every case of persistent belching, the clinician's attention must be called to the possibility of aerophagy. This is especially true if the patient can belch seven or eight times in succession, and particularly if he can do this when he pleases.

Such patients always wear their clothing loose, to give the abdominal wall sufficient room. The eructations may begin at any moment and continue for several minutes or hours. At first the belching is slow and practically noiseless, but it soon becomes more rapid and loud, so that not only the patient but also the whole household is disturbed. By close observation the physician will notice that the patient collects a little saliva in his mouth, slightly flexes the head on the thorax, closes his mouth and swallows. By this procedure the air is forced into the esophagus, producing a sound which leads the patient to believe that the act is an eructation, while just the opposite is the case. On opening the mouth the air is noisily belched, and then swallowing and eructation follow closely on each other almost continuously. At times it requires eight or ten swallowings of air to induce one good eructation.

Attacks of aerophagy usually occur after meals, and may continue from fifteen to thirty minutes. The thyroid cartilage, it may be observed, rises and falls alternately as in deglutition. Any excitement or shock may induce an attack.

In cases of aerophagy, fermentation or putrefaction of the gastric contents need not be considered. When the gas has been analyzed it has been found to consist simply of swallowed air that has been thrown off. This finding is confirmed by examination of the gastric contents removed by the stomach-tube.

The entering air does not always pass to the stomach; not infrequently it remains in the esophagus and is from there ejected through the mouth. Occasionally a large quantity of thin, glairy mucus is expelled at the same time.

Sometimes the swallowed air is retained and the stomach assumes the shape of a balloon. Grave consequences may result from this accumulation. The persistent distention may so interfere with the circulation of the blood as to inhibit gastric secretion, and a paretic condition may ensue. Pain soon appears, all the symptoms become worse, and the whole process results in an acute dilatation of the stomach. This condition may be serious when it occurs following major surgical operations, particularly on the stomach. This is comparatively rare, because patients are usually able to belch the air.

Aerophagic patients are often treated for various forms of indigestion without benefit, because the cause of the difficulty is overlooked. They usually regurgitate part of their food and suffer from malnutrition. Their mental condition is disturbed and their nervous manifestations are manifold.

At times the air passes through the pylorus, causing a distention of the intestine. It passes quickly through the small intestine and remains in the colon. Part of it is absorbed or, if not too abundant, all of it will be taken up and eliminated through the lungs.

During an acute aerophagic attack, patients may suffer from dyspnea, tachycardia and cyanosis. These are instantly relieved by introducing the stomach-tube, which allows the air to escape. The distention of the stomach with air pushes the apex of the heart upward and to the left. This pressure on the ventricles rotates the heart on its axis and distorts the great vessels at its base. The distended stomach or esophagus may disturb the heart in a reflex manner because the common innervation of these organs is through the vagi. Stimulation of the vagi causes a slowing of the heart. These factors often produce cardiac arhythmias, which become apparent to the patient by periods of different pulse-rate and irregularities, causing them considerable worry and anxiety.

Aerophagy always intensifies preexisting disease conditions. As a complication of gastric ulcer it may cause hemorrhage. It is one of the main factors in postoperative dilatation of the stomach. The clinician must always make sure that patients suffering from gastro-intestinal diseases with gaseous eructations are not aerophagics.

It is of the utmost importance that an accurate diagnosis be made, because the affection is easily remedied. The Roentgen fluoroscope will always show the rise and fall of the thyroid cartilage. This is helpful when one is not sure of his diagnosis.

The examination of the stomach contents in all aerophagics shows the presence of bile. A positive reaction for bile, with eructations, is a pathognomonic sign. The eructation of the air acts as a siphon and frequently draws the bile from the duodenum backward into the stomach. The finding of bile in the gastric contents is decisive. I usually depend on this reaction.

In the treatment of aerophagy, it is necessary to impress the patient with the way he is distending his stomach with air. This can easily be done by telling him to belch and, while this is going on, asking him to keep his mouth open. While the mouth is open he cannot swallow air and the eructations quickly cease. At this stage it is wise to explain to the patient that he has been swallowing air instead of emptying the stomach of gas. In order to keep the mouth open a cork may be placed between the teeth and held there. In this way the air is prevented from entering the esophagus. Then again, in order to keep the thyroid cartilage from rising, one may tie a ribbon moderately tight around the neck; this not only is a direct restraint but also serves as a reminder to the patient.

Hyperalimentation is known to have a salutary effect on weakened patients. Methodic treatment by sounds introduced into the esophagus is sometimes followed by beneficial results. The underlying nervous condition will in many cases yield to electricity, change of climate or hydrotherapeutics. The medicinal agents indicated in this condition consist of the bromides, belladonna, chloroform-water and preparations of valerian.

In cases of aerophagy accompanied by severe pain, opium or some of its preparations are indicated. Suppositories of opium and belladonna serve a good purpose. At the same time the disease which aerophagy accompanies must receive careful attention. The cases of chronic gastritis receive lavage and the ulcer cases their treatments. The neuroses require the most careful consideration. Alkalies and acids are necessary as the functional examination of the gastric contents may indicate. When the air remains in the stomach and cannot be expelled, the stomach-tube should always be employed. As a rule, the psychic treatment brings about complete recovery from the aerophagy itself.

CONCLUSIONS

1. Continued belching of gas for a considerable length of time indicates aerophagy.
2. All eructated gas consists in the main of atmospheric air swallowed in attempting to belch.
3. Aerophagy accompanies many neuroses and is a frequent symptom of functional and organic disease of the gastro-intestinal tract.
4. The presence of bile in the stomach content with eructations is suggestive of aerophagy.

Fatigue.—Work performed by any of the body-cells produces waste-products and other changes in the cells. Up to a certain limit, work, with the resulting changes in the cells, is beneficial and improves the physical condition of the cells, but when the work is excessive, too prolonged, or too fast, waste products begin to accumulate, the cells become exhausted, the proper changes fail, and if the cells are not properly rested, damage results. If the work is continued without proper rest early breaking down and failure of the individual to perform his task are the final results.—B. S. Warren in *Pub. Health Rep.*

MEDICAL VERSUS SURGICAL TREATMENT OF PYLORIC STENOSIS IN INFANCY*

L. EMMETT HOLT, M.D.
Professor of Diseases of Children, College of Physicians and Surgeons (Columbia University)
NEW YORK

Nearly all that we know of pyloric stenosis in infancy has been contributed since 1897. It seems surprising, in view of the definiteness of the clinical picture and the frequency of this condition as shown by the number of reported cases since that time, that it was so long unrecognized; even now it can hardly be called common, although almost every one in active public or private practice among infants is likely to meet one or more cases each year.

My own experience with pyloric stenosis of infancy includes fifty-seven cases, of which number eighteen were seen in private practice and the remaining thirty-nine were inmates of the Babies' Hospital. The steadily increasing number of cases seen would seem to indicate that we now often recognize this condition where formerly it was overlooked.

Pyloric stenosis in infancy presents many interesting and curious features. In the first place, it occurs nearly always in those who are breast-fed. In one of my cases the previous feeding is not given; of the remaining 56, 52 were breast-fed; of these, 40 had nothing else, while 12 had some breast-feeding and some bottle-feeding; only 4 had nothing but the bottle. Bad feeding can hardly be invoked as a cause of this condition — a point of considerable importance in distinguishing it from gastric indigestion, which its symptoms most frequently resemble.

The predominance of the male sex has been noted by all writers. Of 55 cases of my own in which the sex was noted, there were 49 males and but 6 females. No reasonable explanation for this difference has yet been suggested.

SYMPTOMS

The condition is frequently spoken of as congenital stenosis of the pylorus; yet it is very exceptional for the symptoms to be seen soon after birth or even in the first week. I have seen several infants with persistent, forcible vomiting beginning on the first day of life and with other symptoms which were suggestive of pyloric stenosis; but not one of them proved to be examples of this condition. Such an onset speaks strongly against this diagnosis. In four-fifths of my cases the first definite symptoms began in the third, fourth or fifth week and in only two during the first week of life.

In the great majority of the patients the symptoms begin abruptly. The mother can frequently give not only the day, but also the hour when the symptoms began. An abrupt onset of forcible vomiting with no history of previous vomiting was present in 30 of 57, or over half the cases. In 9 of the remainder there was an abrupt onset of forcible vomiting, though occasional vomiting of the ordinary type had been present for some time before.

This abrupt development of symptoms, coming in most patients some weeks after birth, admits of only one explanation: that in the production of symptoms at least, pyloric spasm plays a most important part.

---

* Read before the New York Academy of Medicine, April 16, 1914.

Again, the complete recovery, or to speak more exactly, the disappearance of all symptoms, which occurs in a certain proportion of instances in the course of a few weeks, points in the same direction. On the other hand, when the stomach has been examined at necropsy, there has, I think, been invariably found marked hypertrophy of the pylorus, principally involving the circular muscular layer, whose fibers are increased not only in size but also in number. It is to this hypertrophy, say the pathologists, that the stenosis is chiefly due. The symptoms according to this view have an organic rather than a functional basis.

It is difficult to reconcile satisfactorily the clinical symptoms and the pathologic findings with either one of these views alone, although one or the other view has been adopted by different writers in support of a method of treatment. Some have sought to escape the difficulties by dividing cases into two groups, hypertrophic and purely spasmodic cases. A study of the cases reported by different writers shows that they do not at all agree with regard to the symptoms on which a case is placed in one or the other category. Some would make the presence or absence of a palpable tumor the differential point, while others contend that a tumor is usually found when the patient is carefully examined by an experienced observer in cases which others would class as spasmodic. Nor can the fact of recovery without operation be considered diagnostic; we know that patients having identical symptoms with those that have shown hypertrophy at necropsy or operation do recover and, so far as one can judge by symptoms, they recover completely.

On the other hand, if spasm were in a large proportion of the cases the only factor, why should recovery be, as we find it, a matter of weeks, often of months? A temporary pyloric spasm undoubtedly occurs in many conditions, as in the projectile vomiting of cerebral disease, *but definite, persistent spasm of the pylorus without hypertrophy* is, I believe, yet to be proved. At necropsy, hypertrophy has been in my experience invariably present. It was found in every one of twenty-six necropsies on this condition made at the Babies' Hospital, the description in the record being almost always as follows: A firm, hard, cartilaginous tumor was present. It would be well if the term "pylorospasm," as defining a group of these cases, were dropped from our nomenclature. Its use as indicating the sole pathologic condition present has led to much confusion of thought on the subject, especially regarding the indications for operation. It is, I believe, responsible for neglect of operation when operation might have saved life.

There has been too much discussion of terms in this disease. No two men will agree in the classification of cases seen at the bedside, for no sharp division into spasmodic and hypertrophic types is possible. The real question is whether or not there exists an obstruction sufficient to endanger the child's life, and how it may best be relieved.

A better division is into mild and severe cases. The two elements, the spasmodic and the hypertrophic, are probably present in every case, sometimes one and sometimes the other predominating. It is my own view that the essential difference between the groups of cases is one of degree rather than a difference in kind, but the same elements are present in the two.

Many points in the pathology of pyloric stenosis are still very obscure, and we find it hard to believe that the spasm is the cause of the hypertrophy, and difficult to explain why it is, if the essential condition is hypertrophy, that symptoms are so infrequently seen during the first ten days or two weeks of life.

When we come to the clinical aspects of the disease, however, we find no such divergence of views. The clinical picture is distinct and with careful observation easily recognized in the great majority of cases. In a typical case an infant, usually breast-fed, who has previously shown few or no signs of disturbance of digestion, begins to vomit persistently and forcibly. These symptoms have their most frequent beginning in the third or fourth week of life, and in most cases the onset is abrupt and without assignable cause. To the forcible vomiting are added marked constipation, steady loss in weight and all the symptoms belonging to failing nutrition. Careful examination reveals definite gastric peristaltic waves and in most cases a palpable tumor in the pyloric region about the size of a peanut. In a certain number of cases the vomiting becomes less and less frequent, all the symptoms gradually abate and the child very slowly regains its lost weight. This may require only a few weeks, but more often it is several months. At other times the vomiting is persistent and uncontrollable, the loss of weight is progressive, and unless surgical relief is given, the child dies of failing nutrition.

DIAGNOSIS

Since the question of exact diagnosis and early diagnosis is so important, the essential diagnostic symptoms may be advantageously considered in greater detail. The most constant and usually the earliest symptom is vomiting. So characteristic is it in these cases, as to the time of its occurrence, the manner in which it takes place and the matter vomited, that one can often make his diagnosis from this symptom alone. It differs markedly from the usual vomiting seen in young babies, in that it occurs soon after nursing, often while the child is still at the breast. It is forcible and projectile; the food is fairly shot out of the mouth, sometimes for a distance of 4 or 5 feet. It is in large amounts, usually the entire contents of the stomach, and generally it is repeated after each feeding. If the vomiting is infrequent and does not occur after every feeding, the amount ejected at one time is often much larger than the amount taken at the last feeding. The frequent regurgitation of small amounts of food is seldom seen. The vomiting is unaccompanied by fever or pain, and in the beginning and usually for some time there is no impairment of appetite. Immediately after emptying the stomach the child may seem so hungry as to take a full feeding. Finally, the vomiting is persistent. Nearly all the changes of food have a surprising effect in temporarily lessening the vomiting, but in a day or two it returns and is as severe as ever.

The waves of gastric peristalsis have been so often described that a repetition is hardly necessary. Intestinal peristalsis may be mistaken for them, though very rarely indeed. In the great majority of cases they are typical, unmistakable and readily made out, though in some they may not be observed unless the patient can be frequently seen and closely watched under the most favorable conditions, the most important one being that observations are made immediately after filling the stomach. Sometimes in hospital patients, though both the doctors and nurses were on the watch for waves, it has been a day or even two days before they were observed. I believe visible gastric peristalsis to be the most important symptom for diagnosis and I should hardly be willing to make a diagnosis without it.

While a palpable tumor cannot be considered essential to the diagnosis, it will usually be found by an experienced and careful observer under favorable conditions. But not always: I have seen men, experienced in these cases, unable to feel a tumor when one was afterward shown to be present, and then again, on the other hand, I have known men to be quite sure that they felt a tumor when none could be demonstrated at necropsy or operation. The tumor is more distinct in the most severe cases and where the obstruction is complete. It may persist for weeks or even months in cases in which recovery occurs without operation. In two of my patients who recovered, it was noted as late as the sixth month of the child's life; the patients were seen at 4½ and 5 years, respectively, and both were well. The tumor is usually more evident just before or during the act of vomiting, and it may not be easily felt at other times. It usually hardens during active peristalsis and may be difficult to feel at other times. It may then rise and meet the hand lightly pressed on the abdomen, somewhat as the spleen may do when forced down by full inspiration. It may be displaced from its usual position and so missed. In my opinion, too much has been made of this symptom not only in classifying these cases, but also in deciding the treatment to be followed. The presence of a tumor, because so frequent, is an important symptom in diagnosis, but the decision as to operation should not rest on finding or not finding it, but rather on how much obstruction is present. While the tumor is naturally more prominent when much hypertrophy exists, in the absence of a palpable tumor we are not justified in deciding that only spasm exists, for operation in these cases has often disclosed a typical tumor.

One of the most important means of determining not only the fact of pyloric obstruction, but also its degree, is by measuring the amount of gastric retention. The child is fed a measured quantity and the stomach is emptied by aspiration three hours after this. The ordinary apparatus used for stomach washing will hardly answer the purpose. The little apparatus suggested by Hess for aspirating the duodenum is much better. A food not coagulating in the stomach in large masses must be given, that is, boiled milk diluted at least twice with barley water or condensed milk, or simply by a barley gruel. If, for example, three hours after feeding, the stomach is found to contain nearly as much as the quantity taken or more than this, or if, after no food has been given all night, the following morning 4 or 5 ounces can be removed, as in a case I saw recently, one may be sure that obstruction exists. A determination of the amount of retention is of especial value in the rather rare cases in which vomiting occurs only infrequently. Aspiration is also useful during the progress of the case medically treated to determine just how well a given food is being taken care of.

As a means of deciding the fact of obstruction and its degree, aspiration of the stomach is in my opinion much more valuable than the Roentgen ray, besides being much simpler and always ready at hand. The Roentgen findings may even be quite misleading. Bismuth may pass out of the stomach, as may food, through an exceedingly narrow opening, and yet the symptoms may be of an aggravated type. It can show at most only the rate of discharge from the stomach, and aspiration can show that quite as well and much easier.

Constipation, as uniformly present, is mechanical and depends only on the absence of food from the intestine. In the severe cases nothing comes through, and the stools resemble meconium. In most cases something does pass and we have simply very small stools which may be fecal. More than once I have been amazed to find at necropsy a pylorus which admitted only a fine probe and yet during life fairly good-sized fecal stools had been present.

Other symptoms are always present in this condition though they are not diagnostic; there is progressive wasting which often amounts to 1 or 2 ounces a day. Its rapidity depends on the completeness of the obstruction. The appetite is often unimpaired until the prostration becomes considerable. Muscular weakness and anemia are proportionate to the loss in weight. There is usually a marked reduction in the quantity of urine, and where there is a complete obstruction there may be anuria for twenty-four hours or more. Under such circumstances I have seen a diagnosis of a renal condition made, the vomiting being regarded as a symptom of uremia.

THE QUESTION OF TREATMENT

Given a fairly definite case of pyloric stenosis in an infant a few weeks old, what treatment shall be advised? At present the profession is by no means in agreement regarding this point. Even among those who have had a large experience with pyloric stenosis a wide divergence of view exists. Physicians have reported quite large series of cases treated by medical measures alone with so low a mortality as to lead to the inference that nearly all these patients recover if properly treated, without resort to surgery. Thus, Robert Hutchison in England reports, in twenty cases treated in private practice, eighteen recoveries. German writers, Heubner, Bendix, Starck and others, also give about the same proportion of recoveries in series of cases treated without operation.

On the other hand, quite an opposite view is taken by surgeons. They consider the disease a surgical one and urge that the patient be turned over to them for operation as soon as the diagnosis is made. They argue that medical treatment in a very large number, probably in most instances, is only a waste of time and that the life of the patient is often jeopardized because the surgeon does not see the case until the general condition has become very grave, while with earlier operation nearly all could be saved. In a recent publication Richter of Chicago reports twenty-two operations with but four deaths.

Pyloric stenosis in infancy is accredited with a general mortality of about 50 per cent. if we accept the reports of those who have written most widely on the subject. Of the 57 cases in my series there were 26 recoveries and 31 deaths, a mortality of 55 per cent. There were operated on 28 patients, with 14 deaths; treated medically 29 patients, with 17 deaths. It should be remembered, however, that three-fourths of these were hospital patients and that every case of pyloric stenosis admitted was included, though a considerable number were in so wretched a condition as to be hopeless, and four were practically *moribund*.

The very bad cases were treated medically or operated on in about equal numbers.

To what is this difference of opinion due? Does it mean that with proper medical treatment surgery is unnecessary, or does it mean that different conditions have been considered by the different writers? In looking over case-reports one is unable to see that there is any very great difference of opinion in regard to the symptoms essential for diagnosis. These are pretty well established, and there is very general agreement among both physicians and surgeons.

Some writers take the ground that cases of pylorospasm do not require operation, but that it may be necessary in cases of hypertrophic stenosis. If a child recovers without operation it is evident, they say, that the condition was one of pylorospasm only. This argument is not very convincing. I have already stated my belief that no sharp division of the cases into spasmodic and hypertrophic is possible either on pathologic or on clinical grounds, and that a better practical division is into mild and severe types. In the former, improvement frequently begins in a few days when proper treatment is instituted, and recovery may follow in a few weeks. In the latter also there is a strong tendency to recover from the symptoms of obstruction, and I believe from the pathologic condition also; but the course is so protracted that, owing to the tender age and feeble resistance of these patients, not a few succumb, although to use a Hibernianism, they would all get well if they lived long enough.

Against operation are the following considerations: A large number recover without it, and the essential surgical risks of operation, even in the best hands, are considerable.

The crux of the whole question between medical and surgical treatment of pyloric stenosis seems to me to be: Are the symptoms and conditions such as to make it probable that the patient will or will not live long enough for the pathologic condition to subside? There are medical risks and there are surgical risks; in the individual case one must decide which are greater; the two must be carefully weighed one over against the other.

MEDICAL RISKS

The medical risks in an infant with pyloric stenosis are not to be ignored; they are, I think, not sufficiently considered.

First, there may be death from acute inanition; this in the most acute cases occurs quite rapidly. I have seen a number of cases with such prostration and so rapid a loss in weight that delay in operation even of a few days would, I believe, have cost the child its life.

Second, there is the danger of marasmus or slow inanition from the prolonged duration of the symptoms. While this risk is not so great in private practice, it exists, and in hospital practice and also among patients in poor surroundings it is very serious. The problem is one of infant nutrition with a very heavy handicap, and the difficulties are often great, even when all possible resources are at our command. There are considerable risks in waiting day after day and sometimes week after week when a child is barely holding his weight or losing but 1 or 2 ounces a week. The physician frequently does not realize on what thin ice he is skating, and how near the danger-line he is. Especially is this likely to be the case if the vomiting has become infrequent and fecal stools are present. It is hard to estimate how much resistance these little patients have. To allow the weight to fall gradually from 8 pounds to 7, to 6, or even lower, is to take great chances; and although possibly the majority of the patients may recover, every now and then an unexpected death occurs without warning.

Third, there is the risk of intercurrent disease developing while a child is in a greatly enfeebled condition. This is a very important consideration in a hospital where treatment must usually be continued from six to ten weeks, and it has some weight even in private practice.

Fourth, there is the risk of sudden death, which may come without any assignable cause. It has happened two or three times in my experience that children who seemed to be doing fairly well have collapsed suddenly and died in a few hours, the necropsy giving no explanation. This has occurred when the food taken seemed adequate so far as its caloric value was concerned, when the weight was stationary or showed only an insignificant loss and when the vomiting had practically ceased.

One other question deserves some consideration in this connection, namely, if these patients get well without operation do they recover completely or does a lesion remain which may subsequently give trouble?

During the last few weeks I have either seen personally or had reliable reports from seven patients who were under my observation during infancy with typical pyloric stenosis and who recovered without operation. One, a boy of 9, has had no gastric symptoms since he recovered from his attack, and is the most robust member of a family of four children. A second is now 7 years old; he had to be fed carefully during the first few years, but for two years past he has "eaten everything" and has had no digestive symptoms. A third, whose active symptoms lasted until he was 8 months old, whose weight at 7 months was but 7¼ pounds, and whose pyloric tumor was noted as late as the seventh month, was, at 5¼ years, a husky boy weighing 60 pounds. There had been no gastric symptoms since he left the hospital at 9 months of age. The same was true of three others seen, whose ages were 4½, 4¼ and 3½ years, respectively. None had had gastric symptoms since infancy; all were well developed, and two were robust. A report from another child, 17 months old, tells that his weight was 30 pounds and that he had been absolutely free from symptoms since he left the hospital at the age of 3½ months. These include all the cases of recovery from pyloric stenosis without operation which I have been able to follow. In no instance was there a persistence of symptoms into childhood. After these children recovered from their malnutrition their subsequent progress and development was quite average. The period of malnutrition lasted in most of them until they were nearly a year old and in some it persisted well into the second year.

Is there any evidence that subsequent trouble does occur in later childhood in these patients? We know that hypertrophy disappears slowly, and we have abundant proof that the cessation of symptoms does not mean that hypertrophy no longer exists. Howland found a typical hypertrophic tumor still present in a child who died of acute diarrhea four months after recovery from symptoms of pyloric stenosis. A patient operated on by Downes at the Babies' Hospital, died of diphtheria six months after gastro-enterostomy; hypertrophy of the pylorus still existed. Morse also has reported a similar case; the child recovered from operation (gastro-enterostomy), but died of acute disease six and one-half months later; the necropsy showed that the pyloric tumor and the obstruction persisted.

Pyloric stenosis in infancy was long overlooked, and possibly, as Graham suggests, we are still overlooking pyloric stenosis of later childhood. He reports a case of pyloric stenosis in a child of 6½ years and cites many others from literature which were proved by necropsy. How often these cases occur, or in what proportion of the patients with pyloric stenosis in infancy these late symptoms follow, we are as yet unable to say. Evidence that they suffered from symptoms of pyloric stenosis in infancy is wanting. I have seen but one case of pyloric stenosis in an older child, a girl of 4½ years; but there was no history of protracted vomiting in infancy, and definite gastric symptoms did not begin until the patient was 3 years old.

A connection between the pyloric stenosis of childhood and that of infancy has been assumed. It is yet to be established that they have the same pathologic basis. The final word on this subject has not yet been spoken, and it may be that further experience may cause us to revise our opinion regarding the ultimate outcome of the cases of pyloric stenosis in which recovery occurs without operation. At present the evidence is that patients who get well without operation recover completely.

SURGICAL RISKS

The surgical risks in operations for pyloric stenosis are partly essential and partly accidental. The essential risks are those of shock, of non-union because of the child's poor nutrition, and the danger of exhaustion owing to the fact that the difficulties of feeding have not been altogether removed by the operation. These dangers exist in every case no matter how experienced the surgeon. Of much greater importance are the accidental risks largely due to faulty technic; these are of course greatly lessened by experience on the part of the operator. Then there are the risks of hemorrhage, of leakage, of obstruction, of infection and other accidents which may follow any abdominal operation. On the whole, it is my belief that the medical risks, particularly in hospital patients, have not been sufficiently considered, and that the surgical risks have been exaggerated. With an operator experienced in these cases and a patient in fair condition, the operative risk is much less than one would anticipate. It is to me a constant surprise to see in these patients how small is the amount of shock of an abdominal operation which rarely lasts less than forty or forty-five minutes. The younger the infants the less the shock appears to be, which perhaps is not to be wondered at when we remember what prolonged operations can be done on a new-born infant with little or no shock.

In private practice, if the best environment, good nursing and proper medical attention can be commanded, I believe that the risks of the medical treatment are small and that very many patients will recover without operation. But there will, I believe, always be a certain number of patients for whom surgical intervention will be required. The favorable conditions such as I have mentioned in private practice can be obtained for only a small proportion of the patients with pyloris stenosis. For the others, if the symptoms are severe, I think early operation offers more chances of recovery. Even if the surgical risks are considerable they are short, while the medical risks are prolonged and the dangers multiply with the duration of the symptoms.

An early diagnosis adds much to the chances of success by any method of treatment. In some cases the symptoms have lasted so long and the condition is so critical in consequence of the rapid loss in weight that immediate operation should be advised as offering the only chance of recovery. Under other circumstances every child should have the benefit of a fair trial with medical treatment. The duration of this in hospital practice will depend on the conditions present. If the symptoms are severe, a day or two may suffice; if less acute, a delay of a week or ten days may be permitted. Operation should be done not because a case is classed as spasmodic or as hypertrophic, but because mechanical obstruction of a dangerous degree exists, whatever its suspected nature.

The indications for operative interference are (1) no diminution of the vomiting or the gastric peristalsis by stomach washing and diet; (2) a steady loss of weight of from 1 to 2 ounces a day; (3) marked gastric retention, and (4) absence of fecal stools. The presence of a tumor I do not regard as essential.

My early personal experience led me strongly to favor the medical treatment of these cases. I was greatly influenced by two or three very conspicuous successes in patients treated without operation, and also by the results of the first seven cases in which I saw operation done, five of the seven having been fatal.

Increased experience, however, has shown that the average case medically treated, unless it shows improvement almost at once, is likely to run a very prolonged course even though the child may ultimately recover. From six to twelve weeks of continuous treatment has usually been found necessary in the cases I have seen. This is in marked contrast to the rapid improvement which has taken place in all the children who have recovered after operation.

In looking over the histories of the patients observed during the past six years, I find that in a constantly increasing number I have advised early surgical interference. My greatest regret in this review is that operation was delayed in so many and in some not done at all. In this connection it is interesting to note the length of life after admission to the hospital of patients not operated on. In fourteen such cases it was as follows: 69 days; 44 days; 24 days; 22 days; 17 days (two patients); 13 days; 10 days; 9 days; 6 days; 5 days; 3 days, and two moribund patients. I feel sure that with our present experience a very considerable number of these patients might have been saved. No doubt the technical skill which the surgeons have acquired in the operation has contributed much to these later results, but our experience in the management of the patients after operation has also been a factor.

The postoperative treatment is very important. Emphasis should be laid on four points: hypodermoclysis, feeding, castor oil and posture.

Hypodermoclysis is useful immediately before or after operation as a means of introducing water into the body. It is greatly to be preferred to the Murphy drip. I have employed a normal saline solution with 4 per cent. dextrose; of this from 100 to 200 c.c. are slowly introduced either between the shoulders or into the abdominal walls.

In feeding, breast-milk is indispensable. We begin food as soon as the child has fairly recovered from his anesthetic, or about four hours after operation, giving 2 teaspoonfuls of breast-milk every two hours, alternating this with 2 teaspoonfuls of boiled water. On the following day the interval is made three hours, and the milk and water are each increased to ½ ounce. At the end of forty-eight hours, 1 ounce of breast-milk is given every three hours alternating with 1 ounce of water. By the end of a week the child is usually taking from 2 to 3 ounces of pumped breast-milk every three hours alternating with boiled water. By the tenth or twelfth day in most cases the child is put to the breast, but the amount of milk allowed is limited for the next week or two.

A teaspoonful of castor oil is administered at the end of thirty-six hours and is usually followed by free evacuation from the bowels, which in many cases have not been freely moved up to that time.

The child's bed is inclined at an angle of about 135 degrees or more, the head being raised. This posture facilitates the expulsion of gas from the stomach and greatly diminishes the chances of vomiting. The child is usually kept in this position for four or five days.

CHOICE OF TREATMENT

Whether in a given case we shall decide in favor of operation or medical treatment will then depend largely on the severity of the symptoms and the conditions under which the child is seen. To subject every infant with pyloric stenosis to so serious an operation as laparotomy for a condition in which at a low estimate 50 per cent. recover without it, seems hardly justifiable. I believe it to be a mistake to turn every case over to the surgeon as soon as the diagnosis is made, as some would have us do. On the other hand, the position taken by Hutchison, that "operation is never under any circumstances justified" in these cases is, I believe, untenable. I do not think that the physician realizes how well these patients do surgically, or that the surgeon appreciates how many of them recover when treated medically.

Given an early diagnosis, a patient in private practice under conditions which make the best medical treatment possible, operation may not in most cases be required; but in hospital practice, in cases seen late, in those with the most acute symptoms who are losing rapidly, and when circumstances do not admit of the best medical treatment, there is no question in my mind but that immediate resort to surgery offers a better chance of recovery. Again, to persist with medical treatment week after week when forcible vomiting and marked peristalsis are either continually present or keep recurring, when the weight shows only a slight loss, seems to me to be incurring far greater risks with the child than those of operation.

The medical treatment for patients not operated on consists in careful feeding and stomach-washing. The gastric lavage should be practiced twice a day; it serves the purpose of emptying the stomach thoroughly of mucus and fermented food; the water should be used warmer than usual, that is, up to 112 F. If it can be secured, breast-milk is the preferable food, but one not rich in fat is essential. The common practice of weaning as soon as symptoms develop is most unwise. In default of breast-milk a modified milk mixture low in fat should be employed.

With respect to quantities and intervals of feeding, cases respond differently. We have usually depended on from 1 to 3 ounces at three- or four-hour intervals, water being given in small quantities between feedings. There are seen, however, some children who seem to do better on much smaller quantities, that is, ½ ounce every hour, especially if the food is breast-milk. In greatly prostrated patients hypodermoclysis may be used twice a day as described in the postoperative treatment. Rectal feeding is little assistance except for a very short time. The bowels are moved readily by an enema, and the rectum does not discriminate between those things which are to be retained and those which are to be expelled. At most, it is of assistance only for a day or two. Drugs I believe to be of little or no value, nor can I say more for local applications of heat over the epigastrium as advised by many.

Every case of pyloric stenosis medically treated must be very closely watched; daily weights should be taken, as these children have a way of slipping away unless the most careful observations are made.

Aspiration of the stomach to determine the degree and rate of emptying is of much assistance in deciding the frequency with which these children should be fed and the amount of food offered at one time. Its value is not appreciated.

PYLORIC OBSTRUCTION IN INFANTS

A REPORT OF TWENTY-TWO PERSONAL CASES WITH OPERATION *

WILLIAM A. DOWNES, M.D.
NEW YORK

The intention of this paper is to record as accurately as possible the results in the twenty-two cases of pyloric obstruction in infants which have come under my care. In order to make the report complete, it will be necessary to detail the symptoms for which relief was sought, together with the physical signs leading to the correct diagnosis. Furthermore, the findings at operation and necropsy will be mentioned, for a clear understanding of the pathologic condition present is essential in order that those who are not familiar with the disease may draw correct conclusions. Finally, the operative procedure adopted will be discussed and a critical analysis made of the results obtained.

Of the 22 patients, 17 were males and 5 females; 18 were breast-fed entirely; 2 part breast-fed and part bottle-fed, and 2 bottle-fed; in 14 cases the patient was the first baby; in 4, the second; in 2, the third, and in 2, the fourth.

The symptoms appeared from three days to seven weeks after birth, average time three and one-half weeks. In every case vomiting was the first symptom to be noted, though in one or two instances the mothers recalled that a day or so before the vomiting began there was a loss of appetite, and in one case it had been difficult to get the baby to take its feedings

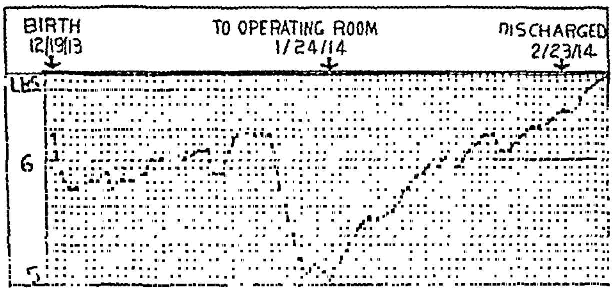
properly from birth. The latter observation is unusual, for as a rule these babies have nursed too freely, taking large quantities at a time. This tendency to overdistend the stomach, with its resulting spasmodic contraction, is considered by some observers as of etiologic significance. The vomiting was projectile and usually occurred shortly after each feeding; in a few cases, however, it occurred at intervals of several hours and was probably the accumulation of a number of feedings. The vomitus was frequently examined for bile, but none was found. Constipation was marked in every case. The first colon irrigation, after admission to the hospital, often brought away small amounts of fecal matter, but those given later on returned clear. The urine was scant or absent. A marked loss of weight immediately followed the onset of vomiting, and in one (Case 6), amounted to 2 pounds in one week. Depression varying in degree from moderate apathy to profound shock was present in all the cases. This condition is the danger-signal, and the first suggestion of it should serve as a warning that the time for radical measures has arrived. One of our patients (Case 10) admitted to the hospital at 6 p. m., examined by me, and the diagnosis of true stenosis concurred in, was somewhat apathetic, but seemed in fairly good condition and it was thought that the operation could with safety be postponed until the following morning. At 6 a. m., twelve hours after admission, the child suddenly became markedly depressed. A state of profound shock supervened, and when I saw the baby at 8:15 a. m., the condition was practically hopeless. Hypodermoclysis and stimulation had been resorted to, with little or no improvement. With a full realization of the very slight chance offered by any method of treatment at this time, a rapid posterior gastro-enterostomy was done, but the condition was not improved, even though feeding was begun in two hours, and the child died four hours later.



Weight-chart in Case 17, illustrating usual gain in average case after gastro-enterostomy.

With four or five exceptions the babies were emaciated, with wrinkled skins and sunken eyes. The lower abdomen was retracted and usually soft, while the epigastric region was full and prominent and all the patients presented at some time, in the region of the stomach, peristaltic waves passing from left to right. While these waves are present in all tumor cases, they may also be present in the so-called spasm cases and should not lead to the diagnosis of true stenosis without other more reliable symptoms and signs. On palpation, to the right of the median line below the costal margin, a firm movable tumor about the size of an olive was felt in each case, with the single exception of the first one, and in this instance the tumor was made out under the anesthetic before the abdomen was opened.

Beginning with the eighth case, aspiration of the stomach was practiced as a routine measure, and each stomach was found to have from ½ to 4 ounces' retention three hours after feeding, even though vomiting had occurred.

We did not consider it necessary or even desirable to submit the babies to Roentgen-ray examination before operation. On account of the extreme irritability of these stomachs, conclusions based on the emptying-time are liable to be misleading, and even if a small amount of bismuth passed through the pylorus, no information would be given thereby that the story of the stools and weight-chart had not already told. Such an examination might possibly be indicated in an exceptional case, but I feel that the diagnostic points already enumerated are sufficiently conclusive. Aspiration has all the advantages of the Roentgen ray in this condition and is more feasible. The average duration of symptoms before operation was performed was two weeks and one day; the longest period was eight weeks and three days, and shortest period six days.

When the abdomen was opened, a pyloric tumor varying in size from the terminal phalanx of the ring-finger to that of the thumb was found in every case. These tumors were hard, smooth, freely movable and free from adhesions. The pyloric portion of most of the stomachs was thickened and somewhat edematous, and about half of them were dilated. No other pathologic lesions or malformations were found. A typical posterior gastrojejunostomy was done in twenty-one cases, and the Weber operation of partial pyloroplasty as described by Rammstedt in one case.

A passing remark as regards a few points in the technic may not be out of place. Ether should be the anesthetic used. The abdominal incision should be from ½ to ¾ inch to the left of the median line. The reasons for this are twofold: In the first place there is so little subcutaneous tissue in these babies that there is difficulty in obtaining union in the median wound, whereas the incision through the rectus muscle heals much more readily. Many postoperative deaths have followed evisceration resulting from non-union in these cases. The second reason for placing the incision to the left of the median line is the avoidance of the round ligament of the liver. At necropsy, in one of our fatal cases, a large hemorrhage was found just where the needle used in closing the abdominal cavity had punctured this ligament.

With the exception of the first two cases, stomach-clamps were not used in doing the gastro-enterostomy. There is practically no leakage from the stomach or intestine, and very little bleeding in these cases. A number of the operations were done in twenty-five minutes — longest time forty-five minutes. The partial pyloroplasty, or "nicking of the circular muscle-fibers," consisted in making an incision 1 inch long through the peritoneum and circular muscle-fiber down to the mucosa. The edges of the wound gaped widely and the mucous membrane immediately protruded. No effort was made to close or cover over the incision. This simple division of the circular muscle at once relieved the obstruction, as shown by the ability to express air freely from the stomach into the duodenum. In making the incision the tumor should be held firmly between the thumb and index-finger in

RECORD OF TWENTY-TWO OPERATIVE CASES OF PYLORIC OBSTRUCTION IN INFANTS

Case No.	Hospital Record Number	Sex*	Age Weeks	Date of Operation	Remarks	Weight At Birth, Lbs.	Weight At Operation, Lbs.	Final Result with Note as to When Last Seen
1	Babies' M. H.	♀	8	4/29/10	Vomiting began in 6th week, always forcible and in large quantities. At same time infant was constipated.	8½	8	Died 11 days after operation; necropsy: Wound healed perfectly; no pathologic cause for death found; pylorus tight.
2	Babies' 3906 D. B.	♂	6	7/30/10	Vomiting began in 4th week; this along with constipation continued till admission. Vomiting always forcible and directly after eating.	11(?)	9 1/16	Discharged Aug. 9, 1910; weight 9 lbs., 5/16 oz.; readmitted Aug. 13, 1910; died Aug. 13, 1910; Necropsy: Gastro-enterostomy perfectly healed; no adhesions; cause of death; acute gastro-enteritis; pylorus tight.
3	Babies' J. S.	♂	23†	11/27/11	Vomiting began on 11th day. One week before admission constipated; no stool without injection.	?	5 21/32	Discharged Dec. 19, 1911; weight 6 lbs., 5½ oz.; last seen Oct., 1913; well-developed and well-nourished child.
4	Babies' 5719 A. F.	♂	7	12/ 9/11	Began to vomit during 5th week; very little relation to feeding, sometimes immediately after, sometimes one or two hours after; usually forcible.	9	7⅝	Discharged Jan. 1, 1912; weight 7 lbs., 14 oz.; last seen March, 1914; walking: condition excellent; weight 30 lbs.
5	Babies' 6627 J. W.	♂	10	8/ 9/12	Vomiting and constipation from 3d week after birth.	?	5 13/16	Died 6 days after operation; necropsy showed no peritonitis; wound in good condition; tumor size of terminal phalanx ring-finger and admits slate-pencil.
6	St. Luke's Newburg, N. Y. C. T.	♂	7	7/ 8/12	Vomiting and constipation 6th week after birth. Vomiting projectile in character. Lost 2 pounds in one week.	8	9	Discharged July 16, 1912; weight 9 lbs. 5 oz.; last heard from Jan. 25, 1914; weight 28 pounds.
7	Babies' G. L.	♂	3‡	12/12/12	Vomiting began suddenly in 7th week; vomited after every feeding; always projectile and large.	8	7⅝	Discharged Dec. 21, 1912; last seen March, 1914, walking; weight 26 pounds; 16 teeth.
8	Babies' 7107 H. L.	♂	7	1/ 1/13	Began to cough and vomit in 5th week. During the 6th week symptoms had become worse, vomited after every feeding.	§	6⅛	Discharged Jan. 28, 1913; weight 6 lbs. 11½ oz.; last seen March 12, 1913; weight 9 lbs. 2½ oz.; excellent condition.
9	Babies' 7127 T. V.	♀	2‡	1/20/13	Typical symptoms began at 2d week of age. Nursed for 5 weeks and for past 3 weeks was fed patented food under direction trained nurse. Admitted in dying condition. Temperature too low to register by thermometer until mustard bath was given.	10(?)	5 11/16	Died 1½ days after operation. Necropsy: Large hard tumor—admits probe—no repair.
10	Babies' 7228 P. B.	♂	7	2/ 9/13	In 3d week sudden onset of projectile vomiting, six or seven times daily, soon followed nearly every feeding. Obstinate constipation and loss of weight.	8	6⅛	Died 9 hours after operation. Necropsy: Large blood clot in transverse fissure of liver from falciform ligament.
11	Babies' 7382 M. C.	♂	6½	3/27/13	Vomiting began suddenly in 3d week, sometimes occurred during feeding, but most often few minutes after; always a larger amount. Condition bad; given mustard baths, hypodermoclysis, etc.	7⅛¶	5 9/32	Died 10 hours after operation. Necropsy: Anastomosis firm. Pylorus admits small probe.
12	Babies' 7651 S. G.	♀	8	6/13/13	Spat up once or twice a day and vomited occasionally before 5 weeks old. Vomits at times while nursing, just afterward, or within an hour. Vomiting is projectile. Three weeks constipation. In collapse at time of operation.	‖	6 7/16	Died 4 hours after operation. Necropsy: Large hard tumor.
13	Babies' 7809 R. J.	♂	4	7/14/13	Ten days before admission began vomiting after nearly every feeding; continued for two or three days, then vomited after all feedings. Vomiting always forcible.	‖	5 21/32	Discharged Aug. 10, 1913; weight 7 lbs. 1 oz. Last seen February, 1914, weight 16 pounds.
14	Babies' D. P.	♂	4	7/17/13	Vomiting began 3d day after birth, and at the end of the first week it occurred during or soon after every feeding; obstinate constipation.	8½	6⅛	Discharged July 31, 1913. Cured, weight 7 lbs. 8 oz. Died Nov. 2, 1913, of laryngeal diphtheria. Condition had been splendid; just before death weighed 15 lbs. Necropsy: Tumor persists, rather small and admits slate-pencil.
15	Babies' 7953 M. G.	♂	6	8/10/13	Vomiting began about one week after birth. Let up during 3d week; recurred and followed every feeding; never projectile.	?	5 9/16	Died 5 days after operation. Necropsy: general peritonitis from leakage; no effort on part of wound to heal.
16	Babies' R. W.	♂	6	12/ 4/13	Began to vomit in the 5th week; always projectile.	‖	9⅛	Discharged Dec. 15, 1913; weight 9 lbs. 7 oz. March, 1914, weighs 13 pounds.
17	St. Luke's 98286 E. B.	♀	5	1/24/14	Vomiting began in the 4th week. Did not nurse well from birth; reached birth-weight on 12th day, but never went over it. Lost 1 lb. and 4 oz. in 6 days.	6⅛	5	Discharged Feb. 23, 1914; weight 6 lbs. 12 oz.; March 27, weight 7 lbs. 11 oz.
18	Babies' W. M.	♂	4	3/30/14	Vomiting began about 20th day after birth, gradually increasing in frequency and force. Became forcible 5 days before admission.	8¾	7⅝	Discharged April 8, 1914; weight 8 lbs. 3 oz. At present the child is in good condition.
19	Babies' J. W.	♂	4	4/10/14	Began to vomit on the 12th day (while nursing) after birth. Weaned on the 21st day. Improvement slight and only temporary on artificial food. Marked jaundice for 4 days before operation, and vomiting became projectile 4 days before operation.	7½	6 15/16	Discharged April 18, 1914; Weight 7 lbs. 3 oz.; jaundice disappeared 4 days after operation. May 10, 8 lbs. 8 oz.
20	Babies' E. H.	♀	5	4/15/14	Up to 2 weeks of age occasional regurgitation. At 2 weeks vomiting started gradually increasing in frequency. Vomiting became projectile 7 days before admission. Nursed up to present time.	?	5 5/16	Discharged April 27, 1914; weight 5 lbs. 15 oz. May 14, 6 lbs. 3 oz.
21	Babies' T. W.	♂	7	4/16/14	Regurgitation one to three times a day started at 4 weeks old. Real vomiting started at 6 weeks; three to five times a day up to 7 weeks old, and then after practically every feeding. Never projectile though slightly forcible on one occasion.	7 7/16	6 11/16	Discharged April 29, 1914; gained 11 ounces.
22	Babies' W. S.	♂	6	4/23/14	Vomiting started at age of 4 weeks and 2 days; once a day for 4 days and then gradually increased in frequency; 3 days before operation vomited after every feeding. Vomiting projectile from the first and usually very large amount.	6	6⅛	Discharged May 5, 1914; gained 8 oz. May 14, weight 7 lbs. 9 oz.

such a way that the edges of the wound are gently drawn apart, and as the incision is deepened a definite line of cleavage will be seen to exist between the pyloric muscle and the mucous membrane. If this point is observed, injury to the mucosa is not likely to occur. Gastro-enterostomy should be the operation of choice in all cases in which the condition of the child is even fair, for the reason that it is an established surgical procedure, the results of which are certain, and the partial pyloroplasty reserved for those cases in which haste is the first consideration. The latter operation is not free from the immediate risk of injury to the mucosa, and its future is uncertain. In Case 20 the recovery of the child has been uninterrupted, but its progress has been much slower than in the other cases.

The after-care of the patients is extremely important, and much depends on the judicious use of stimulants in the form of brandy, atropin and caffein, and also the proper use of fluids by hypodermoclysis and the Murphy drip. That it is not necessary to resort to these measures in the cases which come to operation while yet in good condition is shown by the postoperative reaction and convalescence of a number of the babies in this series, the postoperative course of which reminded one much of the after-history of the average gastro-enterostomy in the adult. Feeding should be started just as soon as possible after operation; small quantities of water alternating with diluted breast-milk were given hourly, beginning as early as the second or third hour in several of our cases. The amount should be increased gradually, and if it is well borne, the child may be put back to the breast in forty-eight hours. It is important to elevate the head of the bed just as soon as reaction is well established, as this facilitates the escape of gas and greatly lessens the tendency to vomit.

A colon irrigation should be given in twenty-four hours, or sooner if there is much distention. The first fecal stool usually occurs from twenty-four to forty-eight hours after operation; if not by this time, from 1 to 2 teaspoonfuls of castor oil should be administered.

I am indebted to the Medical Service of the Babies' Hospital for the privilege of operating in twelve of the cases; the others came through various consultants. In no case have I declined to operate on account of the poor risk. I have not operated for so-called pyloric spasm without hypertrophy, nor do I believe that such patients should be operated on. Two of these patients have been seen in consultation and surgical treatment advised against. Both made good recoveries. There were seven deaths in the series, which must stand on the records as representing the operative mortality. Of the seven patients, three (Cases 9, 11 and 12) were in a collapse at the time of operation and the outcome was to be expected. Our judgment in each instance was against operating, but we had had two infants in almost the same condition (Cases 3 and 8), both of whom came through the operation with little or no additional shock and are to-day in perfect health. A note taken from the history of Case 3, made just prior to operation reads as follows:

> Weight 5 pounds 10½ ounces; temperature 103.2 at 7 a. m., normal at 9 a. m.; child is becoming more relaxed, shows a decided loss of tone. Strychnin sulphate, 1/150 grain, ordered every four hours and a mustard bath three times a day. Vomiting forcible and in large amounts persists. General condition since 5 p. m. yesterday has grown gradually but steadily worse. Pulse is not good; child looks sick about the eyes. P. M. Note: Child prostrated, in a dying condition, rallied slightly toward evening. As a last resort the baby was operated on at 10 p. m.

The history of Case 8 has the following note made on the day of operation:

> This forenoon the appearance of the baby did not seem quite as promising, although yesterday he took all his food except 2 ounces, and stool contained some fecal matter. To-day had one stool (4 p. m.) a dark green-brown stain. Toward evening he did not seem so lively as in the morning; cry feeble, and on the whole decidedly more asthenic. Aspiration showed 1½ ounces' retention—more than any previous aspiration. In view of the fact that the baby has little food coming through as evidenced by his stools, his progressive asthenia, non-response to feeding and inability to pass the duodenal tubes (Numbers 11, 12, 17 French), operation was decided on to-night.

Not to have operated in the three cases above referred to after such a happy outcome as resulted in Cases 3 and 8, would have been unfair.

Patient 1 died on the eleventh day after operation. This baby was given fourteen days of careful medical treatment, during which time the condition was thought to be due to pyloric spasm, as no tumor could be made out. The child became very weak and operation was decided on. Under anesthesia a large tumor could be felt at the pylorus. There was no shock. Small amounts of water were begun after seven hours. Note day after operation says, "Child looks well." The first movement occurred thirty hours after operation, and there were several movements daily from that time until death. There was no vomiting for several days and the child seemed to be on the road to recovery, but about the fifth day after operation the condition became unsatisfactory. Vomiting recurred and in spite of every possible means of relief the child grew progressively worse and died eleven days after operation. Complete necropsy failed to disclose the cause of death. The wounds had healed perfectly and there were no adhesions.

Patient 5 died six days after operation. The indications for operation seemed clear—projectile vomiting, marked loss of weight, palpable tumor, constipation, and the fact that the duodenal catheter could not be passed. The stomach was found to be intensely dilated, the walls thickened and edematous; the tumor was the size of the terminal phalanx of the middle finger. There was no shock. Three hours after operation, the patient began to vomit small amounts. Feeding was begun in ten hours; the first stool was noted thirty-six hours after operation, and during the second day there were seven stools. The patient vomited three or four times each day, the vomitus gradually becoming larger in quantity and projectile. There was no abdominal distention. The patient died on the sixth day. Necropsy showed no peritonitis, and anastomosis firm. The tumor persisted at the pylorus, but the lumen would easily admit a slate-pencil. Possibly the patency of the pylorus in this case, by allowing food to pass through, had something to do with the continued spasmodic contraction. That food entered the intestine freely was shown by the size and quality of the stools.

Patient 10, weight 6 pounds 2 ounces, although rather feeble, stood the operation very well, with little or no shock. Small quantities of water were begun after three hours. Six hours after operation the patient's condition became critical; four hours later the baby died. Necropsy disclosed a large blood-clot in the transverse fissure of the liver, and the hemorrhage could be traced directly to a catgut suture which had been passed through the round ligament. Cause of death was postoperative hemorrhage.

Patient 15, a small baby, weight 5 pounds 3 ounces; did well for three days, but then began to show signs of peritonitis. It died on the fifth day after operation. Necropsy disclosed general peritonitis from leakage, with no effort at repair.

These two cases illustrate dangers of the operation which cannot be overestimated, and show that even though one has had some experience in this work, fatal errors in technic may and do occur.

Of the seven fatal cases, so far as we know, only one had had careful medical attention and treatment from the beginning of the symptoms; most of the patients had made an occasional visit to the doctor or dispensary and a few had been seen by specialists in consultation, whereas, of the fifteen that recovered, nine were private patients, all of whom had been treated skilfully by competent men from the onset of symptoms, and had been seen in consultation by either Drs. Holt, Kimball, Kerley or La Fetra. These cases came to operation after a reasonable time had been spent in attempting to control the symptoms by medical means; the patients were still in good condition, and as a result made practically uninterrupted recoveries. Two patients died after discharge from the hospital, from causes in no way connected with the operation. Patient 2 was discharged twelve days after operation, having gained 4 ounces and was brought back four days later with an acute gastro-enteritis from which it died. Complete necropsy showed the wound in perfect condition and the cause of death to be acute enteritis. In the other fatal case (No. 14), the patient was discharged July 31, 1913, and died Nov. 2, 1913, of laryngeal diphtheria. The condition had been splendid and just before death the baby weighed 15 pounds. Partial necropsy showed that the tumor, which was rather small, but very hard at operation, persisted.

Careful examination of the stomachs removed at necropsy from the patients dying after operation showed that the pyloric tumors were almost exactly of the same size and consistency as they had been at the operating-table, varying in size from the terminal phalanx of the ring-finger to that of the thumb and having the consistency of cartilage. They were formed entirely by the hypertrophied circular muscle-fibers of the pylorus. The mucous membrane lay in longitudinal folds in the lumen. It was much thickened and arranged in a more or less spiral manner.

In view of the experience gathered from the observation of these cases, I believe I am justified in offering the following conclusions:

1. Hypertrophic pyloric stenosis is congenital to the extent that there is an increase in the thickness of the circular muscle-fibers at the pylorus. The presence of this thickened muscle-fiber reduces the lumen of the pylorus, and therefore the stomach, in order to empty itself, contracts more forcibly than normal. This abnormal contraction soon causes the mucous membrane to become thickened and edematous, and assume a more or less spiral arrangement as it passes through the narrowed pyloric channel of from ½ to ¾ inch. The result is a valvular action which gradually produces complete closure of the pylorus. The question as to whether or not the pylorus will admit a probe or catheter at operation or necropsy is of little consequence when weighed against the clinical evidence of complete obstruction.

2. That there is sufficient time between the onset of symptoms and the appearance of the signs of complete obstruction, for careful observation and the carrying out of any medical measures likely to prove of benefit, there can be no doubt, provided, of course, that the early symptoms have been properly interpreted. The fear, however, that the condition may have existed longer than has been suspected, and that the vitality of the baby is not so good as appearances would lead us to believe, makes me feel that operation is indicated in every case of hypertrophic stenosis as soon as the diagnosis is made. Should depression or early evidence of shock be present, immediate operation is demanded.

3. The babies coming to operation in good condition suffer little or no shock; their convalescence is straightforward, and they are at once restored to normal health. My experience in this respect corresponds with that of other operators.

I cannot close this paper without referring to the wonderful results obtained by Drs. Scudder of Boston and Richter of Chicago in the operative treatment of pyloric stenosis. The former has recently reported a series of seventeen cases with four deaths and the latter has a record of twenty-two cases with three deaths.

AN INTERNAL ALEXANDER OPERATION *

HENRY T. BYFORD, M.D.
CHICAGO

Retroversion of the uterus may be associated with general abdominal and pelvic visceroptosis, or it may be due to impaired function of one or more of the so-called uterine supports. In the latter case there is usually a secondary impairment of function of the remaining supports which are, of course, thrown out of normal action in consequence of the abnormal position of the uterus. An operation to relieve such a deformity does not necessarily have to attack all of the overstretched or relaxed structures, for, when the equilibrium of the uterus is restored and maintained for a certain length of time, those supporting structures which are only slightly deficient or are secondarily disabled may often be depended on to resume function. In limiting myself to the discussion of this class of cases, I am assuming that there is no defect in the pelvic floor, or that such defect has been remedied.

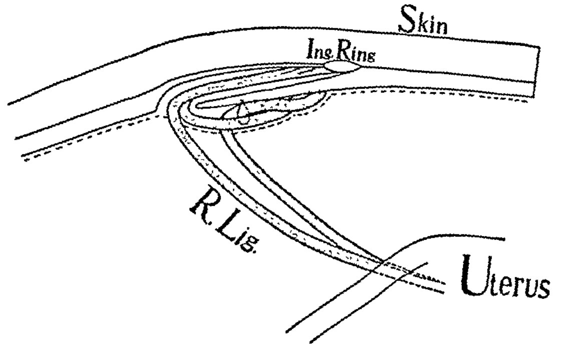
The operation which has proved most satisfactory under these conditions is the Alexander operation. It is one of the simplest of operations, consisting merely of drawing the round ligaments out through their normal channels, the inguinal canals, until the fundus is pulled to its normal position over the empty urinary bladder, and of reattaching them so as to eliminate their apparent excess in length. The part played by these ligaments in connection with retroversion and the Alexander operation is about as follows: The round ligaments are relaxed when the bladder is empty, or nearly so, although they may be supposed to contract more or less irregularly and effectually when stimulated by the shiftings or motions of the uterus accompanying general physical exercise, forced respiration, coughing, defecation, etc. As the bladder fills and pushes the fundus uteri upward, the ligaments are

---

* Read before the thirty-ninth meeting of the American Gynecological Society, May 19, 1914.

put on the stretch and pull gently downward and forward until the emptying of the bladder enables them to contract and replace the fundus. When we consider the fact that they consist largely of muscular fibers and are apt to be temporarily exhausted by steady prolonged resistance, we can realize how retroversion may occur in a person with relaxed pelvic connective tissue who habitually allows the bladder and rectum to become and remain distended. I can conceive how overstretching of the round ligaments can thus become the chief defect, and the relaxation of the tissues behind the cervix may be of secondary importance, and how a restoration to function of the round ligament may become the rational and effective treatment.

When, however, we shorten them, they are not only restored to action, but also made to compensate, to a certain extent, for the relaxation of the cervical supports. We accomplish this by pulling the ligaments taut so that they will not allow the bladder to push the fundus quite so far back. Now if we did nothing more than this there is no doubt but the displacement would frequently recur as a result of the inefficiency of unaided muscle as a steady support, and the delicacy of the connective-tissue structure of the ligaments.



Showing the direction of the normal ligament into the internal inguinal ring, and the shortened ligament folded and attached to the abdominal wall near the internal ring. The dotted line represents the peritoneum.

Hence to render a recurrence less likely we must warn the patient against holding the urine very long, and provide some means of enabling the overstretched sacro-uterine ligaments to contract and regain some of their lost efficiency. A small pessary — one large enough to keep the cervix from coming too far forward during abdominal pressure, and to help overcome the contraction of the vesicovaginal septum due to the prolonged forward dislocation of the cervix, yet small enough to allow of some play of the cervix and thus of some action of the cervical supports — will usually prove a valuable aid to the Alexander operation, and render unnecessary any operative treatment of the sacro-uterine ligaments. On the removal of this small pessary after several months, the cervix is usually found to remain appreciably farther back in the pelvis than it did right after the operation without a pessary.

When the peritoneal cavity is opened by a low median incision for complications of retroversion or for other conditions, we can usually save time by shortening the ligaments through the incision instead of by the Alexander method. But all of the intraperitoneal methods that have been recommended, as far as I have been able to determine, have either proved unreliable or have been associated with objectionable features with regard to their conception or to the resulting complications. The simple folding of the round ligaments is unreliable. Suturing of the folds to the uterus usually produces peritoneal exudates which are often followed by pathologic conditions of the organ with disturbance of its functions. Suturing of the folds to other parts either is unreliable or produces rigid exudates. The passing of the severed ligament, or a loop of it, through the abdominal wall, substitutes a fixed displacement for a changeable one. It is more like carpenter-work than surgery, and is admissible only when circumstances do not allow us to do better. I have not the time here for an enumeration of the objections to each of the numerous methods that have been recommended in our current literature, but they may be classified under the headings, unreliability, adhesions [illegible], abnormal position, restricted [illegible] traumatism, and fundamental errors in conception of objects to be accomplished.

The Alexander operation is freer from these objections than any of the intraperitoneal operative procedures, and in some cases, such as in fat nulliparas, I close the abdominal incision and perform it rather than enlarge the incision and subject the patient to the additional morbidity that so often follows the intraperitoneal methods under unfavorable conditions. The method I now employ, however, avoids intraperitoneal complications and leaves the parts in about the same favorable condition as the Alexander operation. It consists in making a fold near the distal end of the ligament and attaching it intra-abdominally, but extraperitoneally near the internal inguinal ring. Its execution, however, is so simple that a large incision is unnecessary, and it requires much less time, and occasions less trauma than an added Alexander operation. The steps are about as follows:

After the intra-abdominal work for other conditions has been completed, the round ligament is grasped by forceps and pulled out of the inguinal canal until it becomes taut. It is then transfixed by a needle threaded with fine chromic catgut at a point about a centimeter from the internal ring and again about 3 or 4 cm. from the uterine end, and the thread tied so as to make a loop of ligament. The sides of the loop are then sutured with fine chromic or plain catgut forming a sort of double cord. The same is done on the other side and the parts palpated to determine, while there is still time to correct an error in judgment, whether the amount of shortening has been sufficient or excessive.

The peritoneum is next separated freely from the abdominal wall low down on one side of the incision as far laterally as the internal inguinal ring. There is practically no resulting bleeding, and by inserting a short retractor between the peritoneum and rectus muscle one can raise the abdominal wall and do the subsequent work by the aid of sight and touch. With a slender, slightly curved pair of snap-forceps, a puncture from without inward is made in the peritoneal membrane near the internal inguinal ring, and the end of the loop of ligament grasped and pulled through the puncture until the sutured portion of the ligament is all extraperitoneal.

The loop is now given a half twist on itself and, with a curved needle and permanent suture, its base is sutured to the inner surface of the abdominal wall as near the internal ring as possible without danger of puncturing the epigastric artery. The loop of ligament, which is practically a short double cord, can now be horizontally sutured along the abdominal wall with as many or as few absorbable sutures as may seem advisable for the production of adequate adhesions. As the suture that makes the loop is a centimeter away from the internal ring and also from the permanent attachment suture, there is a little play of the ligament at the internal ring and some elastic traction exerted by the normal attachments in the inguinal canal. This play of the ligament prevents the muscular atrophy that takes place in it when it is drawn through the abdominal walls so as to suspend the uterus rigidly.

After the operation has been finished on both sides, the slight oozing of blood that may have taken place between the separated peritoneum and abdominal walls will have ceased and the intra-abdominal pressure will cause a firm coaptation of the raw surfaces as soon as the incision is closed. If the loop of ligament has been drawn carefully through a small peritoneal puncture, the peritoneal cavity will be completely shut off from the space in which the ligament is sutured and this space can be safely disinfected with an efficient germicide. I usually sponge it out with a 1:2,000 solution of mercuric chlorid in case there has been any chance for infection. I have never seen any bad results from separating the suprapubic peritoneum from the abdominal for this purpose.

Should the permanent suture give way and the ligament separate from its attachment to the abdominal wall, the loop will still be held by its subperitoneal embedded attachment, for it cannot suddenly slip through the peritoneal puncture after having grown into it. Nor are the sides of the loop of round ligament very liable to be torn apart after having grown into the subperitoneal connective tissue. Hence the chances of failure are not so great as they would be if the success depended only on attaching the ligament intraperitoneally to the inner surface of the abdominal parietes.

As the only intraperitoneal part of this method consists in making the small loop of ligament and suturing its sides together, and as this loop is drawn through a puncture until it entirely disappears from the peritoneal cavity, and as the ligament pulls from the neighborhood of the internal inguinal ring, I feel justified in saying that the intraperitoneal conditions after the operation, as far as the shortening of the ligaments is concerned, are the same as after an Alexander operation.

Home-Project Agricultural Instruction.—Massachusetts has a law providing for agricultural courses in all state-aided schools. Pupils in the agricultural courses in the schools are required to carry out a certain amount of agricultural work at their homes, under supervision of the schoolteachers during the summer vacation. A number of these schools have been established, and much enthusiasm has been shown by the pupils, and great interest is taken by the parents in these projects. The interest of the pupils in school work is thus kept up beyond the age of 14, when many of them would otherwise leave school. It makes for good citizenship and should have great possibilities for furthering public health and sanitation. A report covering this work has been issued by the United States Bureau of Education as Bulletin, 1914, No. 8.

THE TREATMENT OF TETANUS BY ANTITOXIN

ERNEST E. IRONS, M.D.
CHICAGO

The efficacy of antitetanic serum in the treatment of developed tetanus has been questioned by many experienced clinicians, who have regarded the recoveries in occasional cases of tetanus under large doses of serum as fortuitous; and if one may judge from the lukewarm advocacy of serum in most text-books, the general impression of the profession is that but little can be accomplished by its use. A study of the mortality statistics of most hospitals shows that this skepticism too often has been well founded. Opposed to this pessimistic view are the reports of a number of small groups of carefully observed cases, such as those of Ashhurst and John, in which the evidence seems strong that antitoxin deserved large credit for the recovery of some of the patients, and that the mode of administration of the remedy is a very important element in its success.

The collection of the 225 reports of cases here analyzed was undertaken with the object of ascertaining, in the first place, what results are being obtained in this country with antitetanic serum in the treatment of tetanus, and, in the second place, whether the failures in some cases may not be ascribed to the faulty and inefficient method of giving the serum. Statistical studies of case-reports collected from the literature are necessarily subject to error, and particularly in tetanus, such tabulations have led to conclusions favorable to serum treatment to a degree unwarranted by the actual facts.

With one or two possible exceptions, none of the cases in this series have been reported, and all were obtained by personal correspondence from hospital or private records, for the years 1907 to 1913.[1]

TABLE 1.—MORTALITY OF THE SEVERAL CLASSES OF CASES

CASES TREATED WITH ANTITETANIC SERUM

Incubation, Days	Total Cases	Died	Recovered	Mortality, Per Cent.
5 and less	38	27	11	.....
6	18	15	3	.....
7	21	16	5	.....
8	17	14	3	.....
9	24	17	7	.....
10	13	7	6	.....
	131	96	35	73.28
From 11 to 15	47	22	25	.....
16 and over	22	6	16	.....
	69	28	41	40.57
Incubation known	200	124	76	62.00
Incubation unknown	25	15	10	60.00
Total cases	225	139	86	61.77

CASES TREATED WITHOUT SERUM

Incubation, Days	Total Cases	Died	Recovered	Mortality, Per Cent.
10 and less	12	11	1	.....
Over 10	4	2	2	.....
Unknown	5	5	0	.....
Total cases	21	18	3	85.7

Table 1 summarizes the mortality of the several classes of cases. The mortality in all cases receiving serum is 61.77 per cent.; in 21 cases without serum the mortality is 85.7 per cent. The number of cases in the latter group is, of course, too small to establish a mortality for tetanus, but it agrees with the generally accepted figures of many writers on tetanus, that is, from 78 to 89 per cent. Permin[2] found a mortality of 78.9 per cent. in 199 cases of tetanus without serum; in 189 cases receiving serum the mortality was 57.7 per cent. It appears, therefore, that the mortality is about 20 per cent. lower in patients receiving serum than in those treated without serum.

---

[1] All cases reported by any one observer are included, so far as the completeness of the data permit. The data of 80 cases were obtained by me directly from hospital records. About 20 cases occurred in the private practice of physicians. The remainder were hospital cases, treated for the most part in large metropolitan hospitals, including Bellevue, Massachusetts General, Boston City, Buffalo, Philadelphia General, Royal Victoria and Cook County, Wesley, Presbyterian and Michael Reese in Chicago. To those who have so kindly assisted in the collection of cases my best thanks are extended. A fuller acknowledgment will be made in the complete paper in the Journal of Infectious Diseases.

A further analysis of these cases with respect to the size of the dose, method of giving the serum and duration of symptoms before the serum was given suggests the reasons for failure in some cases.

TABLE 2.—RESULTS WITH RESPECT TO TIME WHEN SERUM WAS GIVEN AND SIZE OF DOSE IN FIRST TWENTY-FOUR HOURS OF TREATMENT*

	Large Doses		Small Doses		Mortality	
Incubation Days	Died	Recovered	Died	Recovered	Large D.	Small D.
A. Cases receiving first serum within 24 hours of first symptoms:						
10 and less	41	13	21	3	75.9	87.5
Over 10	11	15	6	3	42.3	66.6
Totals	52	28	27	6	65.0	81.8
B. Cases receiving first serum in second 24 hours after first symptoms:						
10 and less	11	9	6	0	55.0	100.0
Over 10	2	8	1	0	20.0	....
Totals	13	17	7	0	43.3	100.0
C. Cases receiving first serum over 48 hours after first symptoms:						
10 and less	10	6	7	4	62.5	63.6
Over 10	7	10	1	5	41.1	16.6
Totals	17	16	8	9	51.5	47.0
Grand Totals:						
10 and less	62	28	34	7	68.8	82.9
Over 10	20	33	8	8	37.7	50.0
Totals	82	61	42	15	57.3	73.7

* In this table a small dose = 3,000 units or less subcutaneously; a large dose = over 3,000 subcutaneously or 3,000 or less intraspinally or intravenously.

In the average patient suffering from tetanus in whom symptoms have just appeared, the following conditions are present: Some of the toxin has already reached the central nervous system, and trismus or other evidence of tonic spasm suggests the diagnosis; another portion of toxin is ascending centralward in the nerves supplying the infected extremity; a still larger amount of toxin is present in the blood, and is being taken up and traveling centralward along the other nerves of the body. Some of these patients have already received a fatal dose of toxin in the peripheral and central nervous system when they are first seen, and will die no matter what is done. Patients whose condition is apparently hopeless, however, and in whom convulsions have already begun, may recover, and since, at the present time, there seems to be no criterion by which we may be sure that the fatal dose has already reached the central nervous system, all patients should receive energetic treatment.

The necessity for haste is evident. The toxin still free in the blood must be neutralized as quickly as possible, and for this purpose the intravenous injection of serum is advisable. Next in rapidity of absorption is the intramuscular route, which should be employed if, for any reason, the intravenous method cannot be used. Antitoxin given subcutaneously reaches the maximum concentration in the blood only toward the end of the second twenty-four-hour period after injection. This delay in absorption may entail a lapse of time sufficient to allow the development of a fatal intoxication. It is true that in some cases the formation of the toxin may proceed slowly, so that the subcutaneous injection of antitoxin may prove life-saving, but in the ordinary acute case a dose of from 1,500 to 3,000 units given subcutaneously can be of little immediate value in neutralizing toxin in the blood and staying the course of the disease.

The importance of intraspinal injection of antitoxin as a means of dealing with toxin that has already reached the central nervous system has been recently emphasized by Park, who has shown that animals in which tetanus has already developed may be saved by antitoxin in adequate doses, and that the results are better and smaller doses required when the antitoxin is given intraspinally than when other routes such as the intravenous are employed. These experimental results, together with a number of favorable results in human tetanus, indicate that the intraspinal injection of antitoxin should be urged in all cases of tetanus.

The intraneural injection of antitoxin serves to neutralize that portion of toxin peripheral to the point of injection in the nerves supplying the infected extremity, but from what we know of the distribution of toxin in the body in human tetanus, the instances in which this method alone is life-saving must be extremely rare.

In Table 2 the cases are divided into groups with respect to (1) the incubation period, (2) the time elapsing from the appearance of symptoms to the beginning of treatment, and (3) the size and efficiency of method of injection of the dose of antitoxin. This classification may be criticized as faulty in a number of particulars, but taking the cases in the aggregate, it offers a basis of comparison as accurate as can be obtained from the data available. A comparison of the mortalities of cases receiving large and small doses of antitoxin shows the importance of adequate dosage and proper method of injection. In acute tetanus a small dose of antitoxin given subcutaneously does very little good. The reduction of aggregate mortality over the mortality of untreated tetanus is evidently due to the favorable results obtained in the cases in which larger doses were employed in an efficient manner.

Some comment is necessary on the relative mortalities of cases receiving large doses in the first and second twenty-four-hour periods. The lower mortality in the second group (*B*) is obviously due not to the postponement of treatment, but to the fact that a large number of patients with acute tetanus die within from twenty-four to thirty-six hours after the appearance of symptoms. Such cases will necessarily appear for the most part in the first group (*A*), and the second group (*B*) accordingly will show a lower mortality through this unavoidable element of selection.

Likewise, the third group (*C*) necessarily contains cases with slower onset, milder course and correspondingly less grave prognosis, in which the necessity for rapid neutralization of toxin is less urgent, and the difference between the results obtained by large and small doses of antitoxin disappears. It should be remembered, however, that these cases are distinguishable only after the termination of illness, and the fact that they occur should be given no weight in planning the treatment of the individual case. Every case of tetanus is extremely serious.

---

[2] Permin: Mitt. a. d. Grenzgeb. d. Med. u. Chir., 1913, xxvii, 1.

A similar tabulation of cases with respect to the total amount of serum used in treatment showed essentially the same relation of efficient dosage to lowered mortality.

Magnesium sulphate was given intraspinally in 18 cases which received also serum; in 4 cases, 2 acute and 2 chronic, the patients recovered, giving a mortality for the group of 77 per cent. In 2 cases death occurred shortly after the injection, with symptoms of respiratory paralysis.

SUMMARY

1. From these statistics it appears that the mortality of tetanus treated by tetanus antitoxin is about 20 per cent. lower than the average mortality of tetanus treated without serum.

2. The mortality of cases treated by efficient methods and adequate dose is considerably lower than that of cases receiving small doses subcutaneously.

SUGGESTIONS FOR THE TREATMENT OF TETANUS

The prophylactic value of tetanus antitoxin is established, and needs no argument for its support. That tetanus antitoxin properly used may save the life of a patient in whom tetanus has already developed should be more generally recognized, and the treatment employed in every case at the earliest possible moment. Every hour lost before the giving of the antitoxin decreases the chance of saving life. By no means will every patient recover, but certainly more can be saved than have been in the past five years, and there is every reason to anticipate that with a proper use of antitoxin a mortality considerably lower than that of the present will be obtained.

It is important that the full effect of the antitoxin be obtained immediately, and this may be accomplished by giving, as outlined by Park, 3,000 units intraspinally, and from 10,000 to 20,000 units intravenously at the earliest possible moment after symptoms of tetanus appear. On the following day the intraspinal injection of 3,000 units may be repeated. The blood remains strongly antitoxic for several days. On the fourth or fifth day 10,000 units should be given subcutaneously to maintain the antitoxin content of the blood.

It is doubtful whether the enormous doses given in some cases over periods of many days are any more effective than the more limited dosage outlined above. If only a small amount of antitoxin (3,000 units) is available it should be given intraspinally. Intraspinal and intravenous injections should be given with all the precautions usually enjoined for these methods.

This use of antitoxin in no respect replaces other recognized non-specific methods of treatment in tetanus. Surgical treatment of the site of infection should be instituted at once. The patient should be placed at rest in bed in a quiet darkened room, and should receive sufficient sedatives to control convulsions, together with adequate supply of fluid nourishment and attention to elimination by kidney and bowel. The necessity for large and continued doses of sedatives such as chloral or chlorbutanol should not blind the physician to the possible danger of giving an overdose. The condition of the patient should be carefully watched, and a revision of the standing orders for sedatives made whenever the symptoms suggest the necessity for decrease or increase of dose.

122 South Michigan Avenue.

VAGINAL DRAINAGE

P. B. BLAND, M.D.

Associate in Gynecology in Jefferson Medical College; Gynecologist to St. Joseph's and the American Oncologic Hospitals

PHILADELPHIA

The question of how, when and where to drain is still a matter of constant debate, and a general or universal law of how, when and where has not been established. In the modern trend of surgery, with the growing tendency to "close without drainage," there is no auto-interrogation more often propounded by the operator than "Shall I or shall I not?" I doubt whether the leaning to the more common practice of "I shall not" is the wisest, most comfortable and safest plan for our patients. This question, however, cannot be decided affirmatively by answering that the results justify the means, because the general improvement in surgical skill and aseptic technic certainly must be taken into account.

Heretofore, too many patients were drained, but I fear that we are now approaching the danger-point at which drainage is not practiced sufficiently. Successful issues in cases in which drainage has been considered, unfavorably decided against, and therefore discarded, have and will continue to lead operators to try greater hazards until a calamity befalls, when they run to cover in the opposite extreme of more generous and general drainage. While the teaching of Keith, "when in doubt, drain," is not of so grave importance as it was in his time, it is still worth remembering, and its milder application to surgery to-day will, in many cases of doubt, give the surgeon confidence and his patient more comfort and hope for the future.

It is not the object of this paper, however, to discuss in detail the broad subject of drainage, but rather to limit its scope to the consideration of the drainage of the female pelvis. It is hard to conceive why there should be a division of opinion in selecting the route through which the pelvic cavity of women should be drained. The majority of surgeons, I believe, realize the advantages of drainage through the vaginal channel, and practice it more commonly than ever before. A great number of men, however, persistently cling to the abdominal route and are reluctant to discard this system and adopt the plan which Nature has provided in the vaginal canal.

The failure of some men to select the vagina as a drainage channel is due largely to the fact that they are wedded to custom and fail to recognize, by impartial trial, the advantages offered by utilizing the drainage tract provided by Nature. Would not the more general practice of vaginal drainage of pyogenic infections, involving the pelvic organs, be associated with a less number of infected incisions; would not reopening of the abdominal incision be less frequently required; would not this method bring to the surgeon a less amount of worry, and would not the patient suffer less discomfort, would not her convalescence be more expeditious and calm, and could not one give unquestionably greater assurance of a successful issue in doubtful cases? I fail to see the wisdom of draining pyogenic infections of the pelvic cavity through the abdominal incision, as this method positively has many disadvantages which cannot logically apply to drainage established through the vagina. Therefore, when drainage of the female pelvis is contemplated the vaginal route should be the method of choice.

DISADVANTAGES OF ABDOMINAL DRAINAGE

Abdominal drainage, as has been intimated, has many objectionable features, because it is associated with questions both of economic and vital interest to the patient. No claim can be made for it as a safer procedure than vaginal drainage, and it is of extreme economic moment to the patient, because of necessity it means a prolonged convalescence, and therefore, a longer domicile in the hospital with the additional expense entailed thereby, and a longer period of isolation from remunerative occupation. Besides, it is associated with a greater degree of discomfort than vaginal drainage, and is infinitely more painful and distressing because the abdominal wall is constantly soiled and irritated with material drained. (No objection can be made to the statement that there is a greater danger of infection, more or less general, of the abdominal incision, with material of an infected nature passing through an angle of the abdominal wound.)

An infected incision, therefore, means, to a certain degree, faulty union with a strong likelihood of a weakened abdominal wall with the probability of a subsequent ventral hernia. Should the wound escape infection, the angle through which drainage has been placed and removed heals not by primary reunion, but by second intention, and this, therefore, will predispose the patient to the development of rupture. Abdominal drainage certainly cannot offer more freedom to drainage material than the natural channel leading from below.

One who has practiced abdominal drainage is constantly reminded of and realizes, with deep concern, the dangers incident to the removal of an abdominal drain, especially of the possibility of breaking up adhesions and scattering infection or tearing bowel or omentum or delivering one or both of these structures into the abdominal incision, with the subsequent formation of more or less extensive adhesions and the probability of intestinal obstruction. Is it not good surgery to institute methods which will insure speedy recovery and a short convalescence with the least possible discomfort and the avoidance of subsequent harmful, painful or even surgical sequelae? These ideals of surgery will not accrue from the hard-and-fast rule of abdominal drainage. Many of these ideals can be brought about by the practice of utilizing Nature's tube. It is not at all too much to contend, therefore, that many of the disadvantages mentioned above can be materially reduced and, in the majority of cases, entirely obviated by the practice of vaginal drainage.

In a discussion of this subject at a recent meeting the statement was made that one of the principal disadvantages of vaginal drainage was due to the fact that the drain could not be allowed to remain so long as it could in the abdominal incision, for the reason that "it became foul and offensive." Nothing could be more erroneous than this. The foulness of a drain does not depend on the length of the time it is allowed to remain in the field of operation, but rather on the character of the infection present at the time of operation. A necrotic colon infection will cause drainage material to become foul and offensive, it does not matter where it is located, whether in the vagina or in the abdominal incision. Moreover, foulness does not cause harm. It is a good sign that offensive material is being carried away, and surely it is better to have material of this character without than have it manufactured and pent up within. Indeed, it is not the drain that is foul, but the material the drain is carrying away.

A very important question in this connection is, How long should the drain remain? It is my practice and established rule never to remove, or allow to be removed, a vaginal drain under six days, and I frequently allow it to remain for eight or ten days without any harmful results. It should not be removed too early because the walling-off process by adhesions about the drain is not firmly formed, and therefore, there is a greater danger of breaking up Nature's delicate bands and of disseminating infection. Moreover, if the drain is allowed to remain for several days it is not necessary to repack or redrain.

RULES FOR VAGINAL DRAINAGE

In cases of extensive pyosalpingitis and pelvic peritonitis with dense adhesions and infection limited to the structures below the sacral promontory, I believe that drainage should be instituted and that failure to do this will in many instances cause grave alarm in a stormy convalescence and occasionally result in a fatality. Furthermore, I am convinced that the route to be selected should be through the vagina, with the abdominal incision thoroughly and completely closed. I admit, however, that in a few exceptional cases, it would be good practice to institute both vaginal and abdominal drainage.

In conditions such as mentioned above it has been my custom to begin the operation with a premeditative view of establishing drainage, by making a preliminary free posterior vaginal incision. This procedure has the additional advantage of frequently allowing the escape of unsuspected free exudate, and thus, to a certain degree at least, safeguarding the patient from dissemination. After the posterior vaginal wall is freely incised and accumulated material allowed to escape, the cavity of Douglas is cleansed by gentle dry sponging, after which a tampon of plain gauze is placed in the pelvic cavity. This is allowed to remain until after the abdominal incision is made when it will prove, in a measure, a guide to the operator and in many cases point out to him the lines of cleavage in separating existing adhesions.

CHOICE OF DRAIN

It has long been taught that iodoform gauze does not prove an efficient drainage agent, because it hampers drainage and tends to "dam up." This in a measure is true, but in conditions such as we encounter in pelvic infections it is the ideal drain, for the reason that we need an agent that will afford a certain amount of drainage and at the same time act as a compress to control oozing from the raw surfaces left as a result of separating the dense adhesions. I can see no advantage in the T-shaped rubber tubing. One of the prerequisites of a suitable pelvic drain is the power of the drain to act as a compress and, of course, it goes without saying that rubber tubing will not accomplish this purpose.

METHOD OF DRAINING

After completing the removal of the diseased organs such as the uterus, ovaries and tubes, and other necrotic tissue, the pelvic cavity is thoroughly cleansed by dry sponging, and the tampon, previously introduced from below, is removed. A large tampon of iodoform gauze 1 yard long and 1 yard wide, rolled loosely (not tightly) on itself, with all selvages turned in, is then carried into the pelvis, one end of which is made to enter the opening previously made through the posterior vaginal fornix. There should be no set rule, however, as to the dimension of the gauze employed, but a quantity sufficient to fill the pelvis and fairly cover all stumps and raw surfaces should be used. This method will prevent to a large degree oozing from raw surfaces left in breaking up adhesions, and by keeping the intestines and omentum out of the pelvis, it will prevent subsequent union between these structures and the pelvic cavity. There can be no objection to the employment of the preliminary posterior vaginal incision, because it is quickly executed and does not endanger any organ if properly performed. Where a preliminary posterior incision has not been made this operation can be done, but with a greater difficulty from above by picking up the vaginal wall with a double tenaculum close to the cervix, and incising freely. It is, however, much easier and much safer to make the preliminary incision from below. The gauze drain should be allowed to remain, as has been stated, from six to eight days and it should then be removed, preferably under short chloroform anesthesia. No repacking should be resorted to and no douches should be given for several days, because of the danger of washing or flushing fluid into the pelvic cavity through the vaginal opening. Douches should not be used for several days and then only if material is present to require douching. If reaccumulation takes place in the pelvic cavity subsequently to the removal of the gauze, spontaneous opening usually occurs through the line of vaginal incision or, if necessary, the cicatrix can be readily broken through by digital pressure.

1621 Spruce Street.

HISTORY OF A TYPHOID CARRIER

MAZYCK P. RAVENEL, M.D.
Professor of Bacteriology, University of Wisconsin; Director, Wisconsin State Laboratory of Hygiene
MADISON, WIS.

In the fall of 1910 Mr. A. moved from Minnesota to the town of G., Wisconsin, bringing with him his wife and three boys. He bought a farm 4 miles northeast of the village. In December, 1909, Mr. A. had been operated on in St. Paul for pyonephrosis, and a tumor mass weighing 5 pounds removed. No bacteriologic examination was made. One of the doctors who assisted at the operation states that six months before he had treated Mr. A. for typhoid fever. About the time of moving to Wisconsin the eldest son had typhoid fever, and soon after the two other sons and their mother came down with the disease.

Mr. B. with his family, consisting of his wife, two boys and a girl, moved from Minnesota to Wisconsin about the same time, having purchased a farm in the immediate neighborhood of Mr. A. While the buildings on this place were being put in order Mr. B.'s family stayed at the home of Mr. A., with the apparent result that first the daughter, and soon after Mr. B. and the two sons came down with typhoid fever.

In the fall of 1911 Miss C., a niece of Mr. A., came from St. Paul to teach in the public schools. She was in the habit of spending the week-end at the house of Mr. A. After six weeks' residence in the town of G. she became ill with typhoid fever.

At the same time a sister of Mr. A. visited him and soon after returning to her home suffered from typhoid fever also.

About Aug. 15, 1911, Mr. D. visited at the home of Mr. A. and took supper with him. September 20 Mr. D. entered a hospital after having been sick for some days, and a diagnosis of typhoid fever was made. His illness began during the first week of September.

In the spring of 1912 two young men, E. and F., who were working at the home of Mr. A., both contracted typhoid fever.

In the fall of the same year Mrs. G., a sister of Mrs. A., accompanied by her son, spent a few weeks at the home of Mr. A. Soon after returning home both contracted typhoid fever.

In the latter part of 1912 or January, 1913, Mr. H., a brother of E., spent a night at the home of Mr. A., and twelve days afterward came down with typhoid fever.

In June, 1913, Miss I., a niece of Mr. A., living near him, suffered from typhoid fever. There had been frequent visiting between the two families.

On or about Oct. 15, 1913, Mr. J. took the Reverend K., his wife and two children to the home of Mr. A. for a visit. They did not take a meal at the house, but the children became hungry and cookies were handed. October 28, the Reverend K. bought butter from Mr. A for table use, and on November 2 Mr. A. and family dined at the home of the Reverend K. On November 11 the two children of the Reverend K. became ill with typhoid fever, and on November 30 Mrs. K and her husband also went down with the disease, Mrs. K. dying.

It thus appears that twenty-one cases of typhoid fever occurred among persons in this community, or those who had visited there, and all of them had been in contact for longer or shorter periods of time with Mr. A.

These facts were called to my attention in June, 1913, and the circumstances were so suspicious that I advised doing Widal tests on the family of Mr. A. Mr. A. himself and one son gave positive reactions. We then shipped tubes of bile to the health officer of the town, asking him to inoculate them with the urine and feces from these two persons. Examination of these tubes showed the presence of typhoid bacilli in the urine of Mr. A., but not in the feces. Subsequent examinations have confirmed this finding. Even after treatment with hexamethylenamin for a considerable period of time the typhoid bacillus can still be isolated from the urine of Mr. A. with a considerable degree of regularity.

In the fall of 1913 Dr. Fred Johnson was appointed deputy state health officer, and since that time the field work on this case has been under his charge, and he has collected a number of specimens for examination.

In considering this run of cases of typhoid fever the question may well be asked, With what degree of certainty can the origin of these cases be traced to Mr. A.? In a few of them, as for example Mr. H., who spent a single night at the home of Mr. A., and of Miss I., who had simply visited, the exposure seems to have been very slight, and it is hard to state with any degree of certainty that the disease was contracted from Mr. A. The period of incubation in the case of Mr. H. was unusually short, although not shorter than has been noted in a number of cases. In the case of Mr. D. the exposure also seems to have been slight. The exposure of the Reverend K. and his family appears to have been sufficient, especially in view of the purchase of butter prepared at the farm, and the period of incubation was such that it is not going far out of the way to connect these cases directly or indirectly with Mr. A.

It must be noted also that all of these patients with the exception of Miss I. are known to have taken food served at the house, and on account of frequent visits it is almost certain that Miss I. had also had food there.

Every effort has been made to exclude other sources of infection. The water-supply of the town of G. was examined and found to be above suspicion. There was no typhoid fever in this community except among those persons who had been in contact with Mr. A. Admitting that a few of these cases are doubtful, it is nevertheless reasonable to conclude that a great majority of them were infected directly or indirectly from Mr. A.

RATIONALE OF THE USE OF ANTISEPTICS AND GERMICIDES IN INFLAMMATIONS OF THE MUCOUS MEMBRANES *

MARSH PITZMAN, M.D.
ST. LOUIS

This paper concerns itself with the question why antiseptics and germicides influence favorably the infections of the mucous membranes. The simplest answer, the one accepted for several decades almost as gospel, is that antiseptics or germicides gradually kill off the bacteria and so terminate the infection. Of course, one can use or misuse an argument at will so long as the world is with one, but the thinking element of the medical profession has become skeptical. Once the bacteria lie in the depths of the tissues, except as to be noted later, a great mass of honest experimental work has shown that it is impossible to reach them with our antiseptics or germicides as used in practice. This demonstration accounts for the honest skepticism and growing discontent with the old explanation.

The general surgeons are going through a similar evolution. The belief that the use of a moist antiseptic or germicidal dressing over an infected wound has any direct influence on the course of the infection within the tissues is rapidly losing ground. The progressive surgical opinion of to-day is that in infected wounds a moist saline or water dressing will accomplish all that an antiseptic could without the risk of the occasional bad effects of the antiseptic or germicide.

First, I wish to make sure that we are agreed on the use of terms. A germicide is a preparation that kills vegetative bacteria on true contact practically instantaneously. Spores require especially strong germicides to bring about their instant destruction, such as free chlorin, intense heat, etc., and consequently are not considered in this definition. An antiseptic is an agent which hinders the growth of bacteria. After hours or days antiseptics often kill bacteria, but do not necessarily do so. The German term, *entwicklungshemmend* — development checking — is much preferable for a clear understanding of the meaning.

PROPHYLACTIC USES

One most important use of the germicides is a by-product of medical science of the last decade. I refer to the prophylactic use of germicides on a mucous membrane which has been exposed to infection. Under such circumstances the bacteria are on the surface and theoretically should be killed off by the proper use of a germicide. The strength of solution which should be used to make sure of killing the bacteria, and at the same time do a minimum of injury to the tissues, constitutes an open question for individual experience and judgment. From the points of view, however, of both theory and the literature, I would strongly favor the use of an active germicide and condemn the weaker antiseptics, such as argyrol or collargol, as not being efficient in killing off bacteria. Credé's prophylaxis of ophthalmia neonatorum, I take it, is accepted as being efficient in killing off the gonococcus on the surface and thus preventing the infection. The original 2 per cent. solution is now held to be unnecessarily severe, so that 0.5 per cent. or even weaker solutions have justly come into use.

The prophylactic use of a germicidal injection after exposure to venereal infection from a theoretical point of view is reasonable. Of late this procedure has gained greatly in the number of its adherents. The more recent army reports are favorable to its efficiency in practice. The exact strength of solution opens a field for individual views, though here again weak antiseptics should not be depended on.

Another direct use of germicidal power belongs to the ophthalmologist exclusively on account of the anatomic structure of the cornea. Because of the density of structure and consequent comparatively limited possibilities of blood- and serum-supply, the cornea is comparable to bony tissue. In such tissues the infection tends to remain localized and so theoretically could be blotted out by the use of a germicide Good authority affirms that it works out in practice.

ACTION IN ACUTE INFLAMMATION

Now I venture into the dangerous field of comparison. Let us take up the established surgical principles in dealing with an abscess. Once an abscess has reached such a size that fluctuations can readily be made out, practically always the fluid contents must be discharged before it will heal. When neglected, the pus often works its own way out; more properly the knife hastens its escape. The rational explanation of the healing is that the tissues no longer have to struggle against so great a quantity of toxin and consequently are able to overcome the infection. It has been often directly proved, of course, that a fresh abscess contains toxin in quantity. Many abscesses will heal, no matter in what part they are opened; others refuse to heal until opened at the lowest gravity point; hence the established surgical rule. This, I should consider, would rule out the question of tension, for tension is relieved as well by a high as by a lowest-point incision. The pus with its toxin must drain out of the wound entirely in order to promote recovery. But certain abscesses cannot, on account of their anatomic relations, be drained from the lowest point; such, for instance, are deep collections, or abscesses in certain joint cavities. The accepted surgical procedure there is to insert tubes and continuously wash out the pus with its toxin as soon as formed—some surgeons advocating normal saline solution, others, I believe not improperly, adding weak antiseptics like potassium permanganate or argyrol.

---

* Read before the St. Louis Medical Society, April 18, 1914.

* My previous papers on similar topics are: Hyg. Rundschau, 1909, No. 12; Fallacies in the Understanding of Antiseptics and Germicides with Special Reference to Mercuric Chlorid, THE JOURNAL A. M. A., July 23, 1910, p. 308; Am. Jour. Ophth., 1912, xxix, 1.

As a basic principle for these well-recognized surgical procedures, we thus find the continuous removal of the toxin. This checks the poisoning, while the antisubstances of the body bring about the cure. In a nutshell, I should consider the same principles as the basis of the modern treatment of acute inflammation of the mucous membranes. The advantage of the addition of mild antiseptics to the irrigation I accept as established by the clinical experience of many excellent observers. Theoretically these weak antiseptics may well aid in cleansing the membrane, and possibly in preventing further toxin formation in the already excreted serum by their antiseptic powers. Stronger germicides in the acute stages are, according to this argument, not helpful, and inasmuch as they increase the irritation, are distinctly contra-indicated.

ACTION IN CHRONIC CONDITIONS

The great advance in the treatment of chronic mucous membrane inflammations in the past decade is due to an improved recognition of the cause of the chronicity. For example, the cauterization of enlarged turbinates when required, putting an end to a nasal focus, may be all that is necessary to end a chronic conjunctivitis. The massage of the prostate or seminal vesicles may end a most persistent urethral inflammation without other treatment. The gradual dilatation of the lacrimal ducts or urethra may be all that is required to cure otherwise intractable cases. The protection of the eyes against any constant irritation may be the sole help which Nature requires. The dilatation of a ureter, or the removal or drainage of a kidney, may be required to cure a chronic cystitis. The reestablishment of complete bladder drainage in cases of prostatic hypertrophy or of prolapsed bladder in women may be indicated. Further, and greatly to be emphasized, a toning up of the general health will often promote a cure when other measures have failed.

So it is obvious that chronic mucous membrane inflammation can be cured without the use of any antiseptic or germicide. In other words, it is unnecessary to kill off the bacteria within the membrane by germicides in order to obtain a cure. The negative results of the honest experimental work are therefore not so disheartening. The statement that silver nitrate solutions, etc., are good for the treatment of chronic mucous membrane inflammations is therefore only in part true. At times it is surely not a necessity of treatment; at other times the belief in its efficacy causes neglect of other most important measures.

In chronic mucous membrane inflammation, after all is done that can be accomplished along the general lines noted above, some degree of irritative treatment is unquestionably called for in a great percentage of cases, to hasten in some, or in others to bring about a cure. What strength and frequency of irritation, whether the very strong germicides or the weakest of astringents, are questions to be decided on the merits of the individual case. Why do these measures cure? Negatively, I feel strongly that they do *not* act by killing off directly the infecting organism. With this opinion the great majority of progressive specialists, I take it, are in full agreement. The benefit is an empirical observation, what in medicine we are wont to call an alterative action. It probably has several factors, an increased blood-supply carrying fresh antibodies, improved drainage of small pus-pockets, a local stimulus to the proliferation of cells, etc.

Germicides in this usage are a two-edged sword, and must be used in the various types of chronic inflammations with the mind open to possible bad effects. For instance, in the midst of a very dense scar it would obviously be impossible to increase the blood-supply. Further, to decrease the discharge for a time artificially by an astringent does not necessarily mean improvement of the condition. But with intelligent observation they are capable of accomplishing real good.

CONCLUSION

It is thirty-odd years since the beginning of the modern study of bacteria, and of antiseptics and germicides. In the enthusiasm of so great a discovery—one that revolutionized the whole status of medicine—it is not to be wondered at that the powers of antiseptics and germicides were exaggerated—that their limitations were not recognized. The battle for antiseptics and germicides has long ago been won, but it remains for the present day impartially to determine their limitations. Many of the veterans naturally are loath to give up their former positions, whereas many of the younger men feel that the general truth of these limitations is too patent to be of interest for discussion. I wish to emphasize my belief that the rationale back of the use of antiseptics and germicides is a live question in theory—one whose answer must have an influence in practice.

Wall Building.

"Pylorospasm".—The "pylorospasm" of the roentgenologist is not the well-recognized pylorospasm of the clinician. Most roentgenologists in writing about the bismuth residue which occurs so frequently in pyloric and duodenal ulcer, speak of "pylorospasm" as if it were a fact and not a theory. Case, for example (*Jour. Michigan State Med. Soc.*, November, 1913), says "When the meal is larger, delayed pylorospasm may be set up and a small residue remaining longer than six hours may result." Of course, the converse is the true statement: "When the meal is larger, a small residue may remain longer than six hours, and this we assume to be due to pylorospasm." Roentgenologists habitually diagnose pylorospasm when they find a six-hour residue in a highly acid stomach showing clinically no signs of pylorostenosis. They know, however, that it cannot be true. Firstly, in the great majority of cases they can press this bismuth through the pylorus into the duodenum by effleurage with the hand or with the distinctor of Holzknecht. Secondly, a jet of bismuth water will often dash through the pylorus into the duodenum although the residue remains. Most important of all, I have often passed the large Gross duodenal tube through the pylorus in these cases without any difficulty (Lippman, C. W.: Simplification of the Duodenal-Tube Examination, THE JOURNAL, March 21, 1914, p. 911). I have even passed the tube while the six-hour residue was in the stomach in a few cases. Certainly a pylorus which allows a large lead ball to pass is not inclined to pylorospasm. It seems to me that the residue is due to the sinking of the bismuth in the excessive fluid secretion which is so often associated with gastric and duodenal ulcer cases. Most of the men believe that the residue is due to pylorospasm plus hypersecretion, but in consideration of the facts mentioned above, I believe that pylorospasm in its pure clinical sense is a negligible factor in the ordinary case with a six-hour residue.—C. W. Lippman, M.D., San Francisco, St. Francis Hospital.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street . . . Chicago, Ill.

Cable Address . . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance

Contributors, subscribers and readers will find important information on the second advertising page following the reading-matter.

SATURDAY, JUNE 27, 1914

On account of the large amount of space occupied by the index in this issue of The Journal, certain departments have been omitted entirely and others abbreviated.

THE INDEX

This issue of The Journal contains the index to the current, or sixty-second, volume of The Journal, including the current medical literature which has been listed from week to week. The Index contains references to original articles in over two hundred of the leading medical journals of the world, including those of the principal foreign countries.

The Index consists of two parts — an author and a subject index. Under "Authors" appear the names of all who have contributed articles to The Journal or to any other medical journal listed in the current literature, as well as the names of those whose papers are abstracted in the medical society reports in The Journal. Under "Subjects" will be found complete references to all reading-matter in The Journal and references to the original articles in all domestic and foreign journals listed, arranged under the subject of the article with double entry when necessary and with numerous cross-references to facilitate the use of the Index. The figures in bold-faced type refer to reading-matter in The Journal.

The "Guide to Current Medical Literature," under which title the Index appears in pamphlet form,[1] contains, in addition, the titles of the articles listed, arranged chronologically and by journals, as in the Current Medical Literature Department. It is issued in separate form for convenience—to make it unnecessary to handle the bound volume of The Journal.

Just preceding the Index a list of the journals indexed during the past six months is given. Any foreign journal, except those starred, will be lent by The Journal to subscribers and members in the United States with the understanding that it will not be held over three days. Requests for journals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. The addresses of the domestic journals are given, and these can be obtained direct from the publishers. No domestic journal will be lent, as these can be obtained direct from the publishers as easily and as quickly as from us.

DISINFECTION AFTER CONTAGIOUS DISEASES

Advances in our knowledge of the way in which disease is spread are continually influencing our methods of combating infection. An instance of this is best seen in the importance which the living carrier of infection is assuming in the minds of public-health officials, as contrasted with the relative unimportance of inanimate objects or fomites. The question has its distinctly practical side. Given a certain sum of money for combating disease, how can it be most profitably expended? The most fruitful sources of infection should plainly be attacked first, while those of lesser significance may be made to wait for more ample resources or until more vital matters have been successfully dealt with. If the neighborhood of a disease-germ carrier is highly dangerous to uninfected persons, while the inanimate objects with which he comes in contact are not likely to convey disease, this fact should be known in order that our efforts may be directed where they are likely to be most effective. We have no wish to expend any energy fighting windmills.

It is not always easy, however, to secure evidence of the relative efficiency of different methods of combating disease. At present some attempts are being made to study the value of terminal disinfection and to determine what our efforts in this direction are actually accomplishing. It is essential that we know just what the facts are.

Large sums of money have been and are being spent by city health departments in disinfecting rooms after cases of infectious diseases. The custom has in its favor the weight of opinion and the sanction of long tradition, but its efficacy in preventing the spread of infection is now being seriously questioned by some experienced health officers. Every one will admit the theoretical possibility that, in a room once occupied by a patient or convalescent, specific disease germs may remain long enough to endanger its subsequent occupants. Whether disease is actually disseminated by this method is another question, and one that can be settled only by experience. Our knowledge of the life-history of pathogenic bacteria outside the body, while far from complete, is at least sufficient to show that differences exist and that conclusions drawn from observations on one disease cannot be indiscriminately applied to others.

---

[1] The Guide to Current Medical Literature may be obtained from the Association office at 50 cents a copy.

One method of determining the value of room disinfection in preventing the development of fresh cases of infection is to compare the number of cases arising in households after room disinfection with that of cases originating in the absence of such disinfection. Such a comparison has been made by Chapin[1] of Providence, R. I., with instructive results. Two diseases are considered, diphtheria and scarlet fever. In Providence, a city of about 235,000 inhabitants, "living for the most part in dwellings with tenements or apartments for two to six families," terminal disinfection after scarlet fever was discontinued after 1908. A comparison is thus permitted between a disinfection and a no-disinfection period. Cases occurring in the immediate family within sixty days after the termination of isolation were considered recurrences. During the years 1904-1909, when room disinfection was practiced, scarlet fever developed in 2,428 families with 36 recurrences, a percentage of 1.48; during 1909-1912 (no-disinfection period), there were 1,704 infected families and 26 recurrences, a percentage of 1.53. A similar comparison for diphtheria gave a percentage of recurrences of 1.71 in 1,457 infected families after disinfection and 1.75 in 3,658 families during the period of no disinfection. The same conditions are shown by a similar comparison of the number of cases developing among susceptible persons, mostly children, who had been sent from home during the progress of the disease and returned at the end of the isolation period.

"Between 1889 and 1904, 1,013 persons, mostly children of school age, returned to their homes following disinfection after diphtheria. Of these, nine, or 0.88 per cent., contracted the disease. Since the beginning of 1905, 836 persons, mostly children, have returned to their homes where there had been no disinfection. Of these, seven, or 0.84 per cent., contracted diphtheria. Of these, five were in 1912. Of 1,659 persons who had never had the disease, thus returning to disinfected houses after scarlet fever, twelve, or 0.72 per cent., developed scarlet fever. Of 284 persons thus returning where there was no disinfection, three, or 1.05 per cent., contracted the disease."

These results, taken as they stand, are thought by some to indicate that the costly and time-consuming practice of house disinfection has little or no influence on the spread of infection in diphtheria and scarlet fever. While this is in accord with recent observations on the importance of carriers and missed cases, further investigation of this important question is plainly to be desired.

The recent action of the Department of Health of the City of New York[2] in discontinuing fumigation after diphtheria and measles may be noted in this connection. After room disinfection following diphtheria was abandoned, the practice of taking the bedding to a disinfection station for sterilization was continued; but more recently this procedure also has been dispensed with. Fumigation after scarlet fever is still carried out by the New York Health Department, though the statement is made that the number of secondary cases occurring even in the families directly exposed "is surprisingly small."

Many investigators believe that the life of most disease germs outside the body is very brief and that the danger from inanimate objects or fomites is therefore in most cases slight. Each disease, however, must be studied with reference to its own mode of spread. It does not follow that, because room disinfection appears to some observers of little or no value after diphtheria, scarlet fever or measles, it is also to be abandoned after pulmonary tuberculosis and small-pox. At least one definite conclusion seems justified: many public-health measures are still on an experimental basis and, like any other similar procedure, must be judged by their outcome. Analogy and tradition are not safe guides.

ACIDITY, EDEMA AND NEPHRITIS

The controverted theories of edema and nephritis proposed by M. H. Fischer[1] have awakened considerable clinical interest because of the practical recommendations which have been based on them. Broadly speaking, Fischer's view is that increased acidity is the fundamental cause of most forms of edema, and of all forms of nephritis and albuminuria. The conclusion rests primarily on certain simple experiments on the swelling of fibrin, gelatin plates, fragments of tissue, etc., in alkaline and acid solutions. In these experiments Fischer has observed, in all cases except when very dilute acid was employed, an influence of acidity in increasing the colloidal swelling of these protein substances in the solutions in which they were immersed. From this he concludes, in essence, that acidity may be the cause of colloidal swelling in the body.

Various writers have taken issue with this assumption since it was first presented.[2] The most recent and perhaps most convincing criticism has come from the chemical laboratory of the Massachusetts General Hospital in Boston.[3] This points out what has been emphasized before, namely, that nowhere in the living body (except in the gastric juice in which the swelling of protein in acid is indeed a factor of importance) has a single instance been detected of such acidity of reaction as occurred in Fischer's fundamental experiments. On the other hand, even in his own trials, no significant swelling — the index of the edematous state — ever occurred with acidities represented by a hydrogen-ion concentration of less than 0.0005 normal. The highest acidity of the urine ever reported, however, expressed in these terms, is less than 0.00003 normal hydrogen-ion concentration, and only very rarely indeed does this value exceed 0.00001 normal, even in severe acidosis. These figures for the urine are, in turn, at least one hundred times larger than those for the blood in extreme acid intoxication.

[3] Henderson, L. J.; Palmer, W. W., and Newburgh, L. H.: The Swelling of Colloids and Hydrogen Ion Concentration, Jour. Exper. Pharmacol., 1914, v, 449.

In a series of new experiments, L. J. Henderson and his colleagues[3] have now shown that there never is the slightest measurable influence of variation in hydrogen-ion concentration, within the ranges known to occur in the body or even in the urine, on the colloidal swelling of such substances as Fischer used in his experiments. All instances in which colloidal swelling has been observed as a result of acidity are cases in which the acidity is greater than any concentration of ionized hydrogen known to occur in the body.

Fischer has pointed out, in confirmation of his theory of edema as based on the colloidal swelling of proteins in acid, that edema actually is known to occur in certain conditions attended with an increased production of acid in the body. It is, however, far from true that, as a rule, a tendency to an abnormal accumulation of acid is accompanied by edema. A normal acidity of low degree is a very common pathologic phenomenon.[4] It is usually quite independent of any known disturbance of the water equilibrium of the organism. Hence the Boston investigators remark that it is utterly fallacious to assume that any causal significance attaches to the frequent tendency in edema toward the occurrence of acidity. The tendency to either high or low acidity may be associated with the presence or the absence of edema.

Again, according to Fischer, albuminuria and nephritis are characterized by colloidal swelling and dissolution of renal tissue through the action of the increased acidity or tendency to acidity which is the alleged essential factor in the disease. From this he concludes and recommends that the entire purpose of our therapy in the relief of the acute nephritides must be "to get alkali into the patient in order to neutralize the acids present; to get salt into him to aid in the reduction of the edema of the kidney (and other organs); and finally, to give him water in large doses at regular intervals in order to have 'free' water available for urine." For these purposes it is advised to administer either by mouth or by rectum, or even intravenously, properly concentrated solutions of sodium carbonate and sodium chlorid. Against this, Henderson, Palmer and Newburgh have offered a protest, insisting that the medical treatment which is founded on this view is both harmful and productive of human suffering. They point out that although it is true that there is an increase in the hydrogen-ion concentration in the urine in nephritis, it is also true that a similar increase is shown in many other diseases in which neither nephritis nor albuminuria occurs. There is no known connection between the hydrogen-ion concentration of the urine and its protein content. It is possible to make the urine alkaline without effect on the concentration of protein, and albuminuria may even be caused by the ingestion of sodium bicarbonate. Either in the presence or in the absence of edema the administration of this alkali may be followed or not followed by diuresis.

Current Comment

ASSOCIATION PROCEEDINGS

It has been the custom to publish a part of the minutes of the Annual Session of the Association in The Journal the week of the meeting. This year no attempt is made to follow the previous custom, for two reasons: first, this issue being the Index Number, there would be space for only a small part of the minutes; second (and the main reason), this is the last number of the volume, and if part of the minutes were printed here and part in the next issue, they would appear in two different volumes, which would be awkward for future reference. The complete report of the proceedings will appear next week.

RECENT FINDINGS CONCERNING GLANDERS

It is sometimes quite as important to record failures as to proclaim the promise of success when some new procedure is introduced in medicine. For this reason we may refer to the tentative conclusion of the Bureau of Animal Industry[1] that the attempted methods of immunization of horses with glanders vaccine have given unsatisfactory results in the hands of the government pathologists. The dangerous character of glanders and the possibility of its transmission to man render every effort to control and eradicate this disease in horses of interest and importance to the physician as well as to the veterinarian. When artificially infected, the vaccinated animals showed no resistance. For the present, therefore, we are warned by the Washington Bureau that it seems advisable to abstain from immunizing horses by this method, as a practice of this kind may do more harm than good. Owners having horses which are supposedly immunized would naturally become careless, thinking their animals were resistant to the disease, and thus even a better opportunity would be offered for the propagation of the disease than if the horses were not vaccinated. Furthermore, the fact that the blood of vaccinated animals cannot be utilized for serum tests for two or three months after the injections is also a great disadvantage in the eradication of the disease. As a result of this preliminary work it appears that the control and eradication of glanders must still depend on the concentration of our efforts to eliminate infected horses and to adopt proper precautions against the introduction of infected animals into stables free from the disease. The results achieved in Germany, Austria and Canada by these methods have proved very encouraging, and no doubt if executed in the same spirit in this country a marked reduction in the number of cases of glanders would result.

---

PUBLIC EDUCATION BY UNIVERSITIES

A striking illustration of the changing conditions in educational ideas may be found in the growing appreciation on the part of leading universities of their responsibility to the public. In former generations a university was regarded as a thing apart, and a college professor was looked on, not only by the humorous paragraphers of the newspapers, but also by the mass of people, as a man living in a world of ideas, without any connection with practical affairs. To-day our leading universities are recognizing not only the opportunity, but also the duty of making available their knowledge for the benefit of the masses. This tendency is highly commendable, especially in the field of public health and prevention of disease. The Harvard Medical School has a standing committee on public lectures which arranges each year for a course of Sunday afternoon talks by members of the faculty. These talks are open to the general public and are on topics of general interest. For instance, last year the course of twenty lectures included such topics as "Preventive Medicine in Relation to Industrial and International Concord," "The Care and Feeding of Young Children," "What the State Board of Health is Doing to Protect the Health of Its Citizens," "The Dangerous Effects of Patent Medicines" and "The Preservation of the Natural Teeth." This year's course includes talks on "Rational Baby Feeding," "Bodily Effects of Rage and Fear," "Spectacles and Eye-Glasses, Their Use and Abuse," and other subjects of practical interest. The lectures given in the past have proved of value and so popular that they are now being issued in little pocket-sized volumes at popular prices under the title of "Harvard Health Talks." In Minnesota the daily press is cooperating in the same kind of work. A series of articles on disease and its prevention by Dr. E. P. Lyon, dean of the University of Minnesota Medical School, recently appeared in the Minneapolis *Journal*. The University of Missouri is one of the few state universities that has recognized the growing tendency by the organization of a distinct department on public health. A series of bulletins for public reading and distribution are being issued. The five so far completed are on "Bacteria and Disease," "The Prevention of Typhoid Fever," "The Prevention of Contagious Diseases in Schoolchildren," "Resuscitation" and "The Relation of Sight and Hearing to Early School Life." Each of these universities has apparently worked out its plans in accordance with the needs of its own particular field. In Boston, popular Sunday afternoon lectures; in Minnesota, newspaper articles, and in Missouri, pamphlets on specific subjects seem to meet existing conditions. The significant fact, apparent in each of these cases, however, is that our universities are recognizing their responsibilities to the public and are making serious, intelligent and practical efforts to meet them.

Medical News

ALABAMA

Monthly Health Bulletin.—Dr. H. N. Rosser, Birmingham, health officer of Jefferson County, announces that he will hereafter issue a monthly report, showing the diseases in the county and the death causes.

Aid Needed for Free Clinic.—It is announced that unless financial aid is forthcoming immediately the free clinic at the Hillman Hospital, Birmingham, will be obliged to suspend. A commitee of physicians has waited on the commission to request an appropriation.

Personal.—Dr. Gaston J. Greil, Montgomery, has been reelected chairman of the executive committee of the Montgomery Anti-Tuberculosis League.——Dr. Andrew Howard Ryan has been appointed full-time assistant in the department of physiology, and Dr. W. A. Clark, assistant professor of anatomy in the University of Alabama, Mobile.——Drs. Charles M. Rudulph, James S. McLester and Arthur F. Toole, all of Birmingham, have been appointed a committee to investigate the extent of mental defectiveness in the state, and to make a report to the legislature for the purpose of obtaining an appropriation for the establishment of a state institution for the treatment of these unfortunates.

CALIFORNIA

Dedication at Children's Hospital.—The open-air porch erected by the teachers of San Francisco at the Children's Hospital as a tribute to Mary Agnes Deane was dedicated with impressive ceremonies, May 25.

Leprosarium on San Clementi Island.—A bill providing for a national sanatorium for lepers is now pending in the House of Representatives. Dr. Edmund O. Sawyer, Los Angeles, health officer of Los Angeles County, is strongly advocating the selection of San Clementi Island as a site for the institution.

Personal.—Dr. Karl F. Meyer has been made professor of bacteriology and protozoology in the University of California. Dr. Meyer's special field of work is tropical diseases.——Dr. Frank B. Carpentier was assaulted by two men in his office in San Francisco, June 9, who attempted to rob him, but were frightened away before succeeding.——Dr. Walter B. Hill, Long Beach, charged with being responsible for the tragedy in which Mrs. Fred Raab killed herself and two children, was fully and completely exonerated by the coroner's jury, June 5.

CONNECTICUT

Centennial of Yale Medical School.—The one-hundredth anniversary of Yale Medical School was celebrated in New Haven, June 15. Special exercises were held on that day in Woolsey Hall, at which addresses were made by Dr. Walter Ralph Steiner, Hartford, on "The Evolution of Medicine in Connecticut, with the Founding of Yale Medical School as Its Notable Achievement," and by Dr. William Henry Welch, Baltimore, on "Pre-Medical Studies in Relation to General Professional Training." Two commemorative volumes are to be published: "The Life and Letters of Nathan Smith," the founder of Yale Medical School, and a special number of the *Archives of Internal Medicine* devoted to articles by graduates of that institution.

Alumni Meeting.—At the thirty-fifth annual meeting of the Yale Medical Alumni Association held in New Haven, June 5, Dr. Seymour L. Spier, New Haven, was elected president; Drs. E. Terry Smith, Hartford; William J. Sheehan, New Haven; Frank L. Phillips, New Haven, and Donald Russell, Wallingford, vice-presidents; and Dr. Marvin M. Scarbrough, New Haven, secretary and treasurer. At the alumni banquet it was announced that pledges had been obtained for the new endowment of the New Haven General Hospital, as follows: for the erection and equipment of a laboratory, $125,000; for the endowment of the hospital, $500,000, and for the endowment of the medical school, $1,100,000, making a total of $1,725,000. Of this amount, $400,000 was donated by members of the Lauder family of Pittsburgh and Greenwich, Conn., and will be known as the Anna M. R. Lauder fund, in memory of Mrs. George Lauder. It is stipulated that a sufficient amount be set aside for the endowment of a public health department, to be known as the "Anna M. R. Lauder Chair of Public Health."

ILLINOIS

Anti-Tuberculosis Clinic Opened.—An antituberculosis cinic has been established in Jacksonville. It was opened for the first time June 9, and it will receive patients from 10 a. m. until noon each Tuesday and Friday.

Memorial Hospital Opened.—The Huber Memorial Hospital, Pana, erected at a cost of $100,000, through the beneficence of the late Dr. Jacob Huber, was thrown open June 13 for the reception of patients. It is a four-story brick and stone structure, is well appointed and thoroughly equipped.

Sanitary Survey of Summer Resorts.—The State Board of Health, with the approval of the governor, has begun a sanitary survey of the summer resorts of the state, which are charged with being responsible for a large proportion of the typhoid cases which exist in the late summer months.

To Investigate State Health Conditions.—At the request of the efficiency and economy committee of the Illinois legislature, P. A. Surg. Richard H. Creel, U. S. P. H. S., is to make an investigation of the sanitary condition of the state and laws under which it is carried on. Surgeon Creel's report is to be made the basis of the recommendation of the committee to the legislature at its next session.

Personal.—Drs. Charles B. Voigt, Mattoon; Londus Brannon, Joliet; Dr. and Mrs. James F. Percy and Dr. and Mrs. Edward C. Franing, Galesburg, have sailed for Europe.——Dr. Jay T. Wood has been elected city physician of Springfield, and Dr. Richard D. Gugan, Illiopolis, physician of Sangamon County.——Dr. and Mrs. Louis J. Frederick, Joliet, have returned from abroad.——Dr. Edgar Hugh Little has been appointed postmaster of East St. Louis.

Chicago

Memorial to Dr. Quales.—The Scandinavian-American Medical Society of Chicago, at its meeting June 11, adopted resolutions regarding the death of Dr. Niles Theodore Quales, setting forth the sentiments of admiration and respect with which his memory was cherished, and extending sympathy to his bereaved wife and family.

Senn High School Dedicated.—The Nicholas Senn High School at Glenwood and Ardmore Avenues was formally dedicated, June 15. Various phases of the life of the "Master Surgeon" for whom the school is named were spoken of by Drs. William A. Evans, P. J. H. Farrell and Truman W. Brophy. An address was also delivered by Ella Flagg Young. A bronze bust of Dr. Senn, which had been presented to the school, was unveiled by Dr. Farrell and was accepted by C. A. Peterson on behalf of the board of education.

Personal.—Dr. Charles W. Leigh, who was in Rochester, N. Y., for the meeting of the American Association of Milk Commissioners, was seized with appendicitis soon after his arrival, removed to the Rochester General Hospital, and operated on. He is reported to be doing well.——Dr. Stephen R. Pietrowicz, formerly superintendent of the Dunning institutions has been appointed a member of the school board.——Dr. and Mrs. Robert H. Buck, Sara Craig Buckley and daughter, and Dr. George H. Miller and family have sailed for Europe.

INDIANA

Site for Tuberculosis Hospital.—Ninety acres of farm land have been bought by Marion County as a site for its tuberculosis hospital, and a committee has been appointed to secure plans for the institution.

Dedication Day Changed.—The dedication day of the St. Francis' Hospital, Beech Grove, which was to have been June 25, has been changed to July 5. It will not be ready to receive patients for several weeks.

Disease Prevention Day.—October 2 has been selected as the date for the observance of disease prevention day throughout the state. The governor is said to have agreed to issue a proclamation regarding the observance of this day.

Colored Physicians Organize.—The Crescent City Medical Society, composed of colored physicians, was organized recently in Evansville, and the following officers were elected: president, Dr. Jeremiah Jackson; secretary-treasurer, Dr. H. R. Thompson.

Donates Site for Colony.—Mrs. George F. Flick has agreed to give the Fort Wayne Anti-Tuberculosis Society a tract of land near the Flick home on which to establish a tent colony for tuberculosis.——On flower day at Fort Wayne, $2,000 was secured for the antituberculosis work by 100 young girls who sold flowers.

Condemnation of Water-Supply.—The water-supply of Madison and that of Bloomington has been condemned by the State Board of Health. At Bloomington, where the State University is located, the situation is so serious that the governor is said to have stated that he would remove the university unless a better water-supply was assured.

Personal.—Drs. James H. Taylor and Horace R. Allen, Jr., Indianapolis, have been seriously ill with pneumonia.——Members and employees of the Indianapolis Health Department gave a thirty-second-degree masonic watch charm to Dr. Mavity J. Spencer, who retired as president of the board June 1. The presentation speech was delivered by Dr. T. Victor Keene.——Mrs. Eva M. Diven, wife of Dr. Charles E. Diven, Anderson, died from pulmonary tuberculosis, June 15.——Dr. William Venable, Carmel, was thrown against a telephone pole in a runaway accident, recently, and seriously injured.

IOWA

Personal.—Dr. James R. Guthrie, Dubuque, dean of the College of Medicine of the University of Iowa, Iowa City, was presented with a loving-cup by his former students, June 17, on the completion of his twenty-fifth year as a member of the faculty of the College of Medicine.——Dr. M. Nelson Voldeng, superintendent of the Cherokee State Hospital, has been appointed superintendent of the recently erected Iowa Epileptic Colony.——Dr. George Donohue, Knoxville, has been appointed superintendent of the Cherokee State Hospital, in place of Dr. Voldeng.——Drs. Ernest S. Heilman, Idagrove; W. Eugene Walcott, Merrill, and David S. Fairchild, Jr., Clinton, have started for Europe.

KANSAS

Personal.—Dr. Arthur J. Anderson, Lawrence, was elected president of the State Board of Medical Examiners at its meeting at Kansas City, June 10.——Dr. J. Edward Graf, Assaria, who was operated on recently at St. Barnabas' Hospital, Salina, is reported to be convalescent.——In the suit of Walter Duckett in the Wyandotte District Court against Dr. Jefferson A. Davis, Kansas City, in which $25,000 damages was claimed on account of alleged malpractice, the jury returned a verdict in favor of Dr. Davis, June 10.

MAINE

Personal.—Dr. Wyvern A. Coombs, a member of the staff of the Central Maine General Hospital, Lewiston, as a result of a competitive examination, has received an appointment as a member of the staff of the Boston Floating Hospital.

State Association Meeting.—The sixty-seventh annual meeting of the Maine Medical Association was held in Portland, June 10-12, under the presidency of Dr. William C. Peters, Bangor. The following officers were elected: president, Dr. Herman L. Bartlett, Norway; vice-presidents, Drs. Albert L. Stanwood, Rumford Falls, and Leander A. Dascombe, Scowhegan; secretary, Dr. John B. Thompson, Bangor (reelected); and treasurer, Dr. Edwin W. Gehring, Portland (reelected).

Eye and Ear Specialists Meet.—The annual meeting of the Maine Eye and Ear Association was held in Portland, June 10. The following officers were elected: president, Dr. Elmer E. Brown, Bangor; vice-president, Dr. Frank Y. Gilbert, Portland; and secretary-treasurer, Dr. Erastus E. Holt, Jr., Portland.

MARYLAND

Personal.—Dr. Hugh H. Young, Baltimore, has been elected first vice-president of the Alumni Association of the University of Virginia. At the recent meeting of the American Medico-Psychological Association held in Baltimore, Dr. Young was elected an honorary member of the association.——Dr. William L. Smith, who has been critically ill at his home at Riderwood, is slightly improved.

Reorganization in Health Department.—The reorganization in the Health Department of Baltimore as a result of the investigation made recently by the United States Public Health Service and a similar investigation now under way by the Bureau of Municipal Research is expected to lead to the abolishment of the present system of having twenty-four health wardens, one for each ward in the city. They will be succeeded by a corps of sanitary inspectors, whose duty it will be to keep the city free from nuisances and to keep yards, cellars and alleys clean. It is contended that physicians cannot be expected to give their whole time and attention to the Health Department matters on the salary of $900 a year now paid them.

MINNESOTA

Health Survey.—Dr. Carroll Fox, U. S. P. H. S., has been detailed to make a survey of health conditions of Minnesota, and to recommend any changes in the system that he may find advantageous.

Promotions in Faculty.—At the commencement exercises of the University of Minnesota, June 11, associate professors Harold E. Robertson and Richard E. Scammon were made professors, and assistant professor Fred W. Schultz was made an associate professor in the medical school.

Tuberculosis Items.—Cottonwood and Noble counties, through their commissioners, have joined the group of counties which purpose to erect a tuberculosis sanatorium for southwestern Minnesota. Worthington and Slayton have been suggested as locations for the sanatorium.——Work on the service building of the State Sanatorium, Walker, is now well under way. The building will contain dining-room, kitchen, laundry, etc. Excavation has been commenced on the general assembly hall and children's pavilion.——The new tuberculosis building of the St. Paul City and County Hospital was turned over to the board of control by the contractors, May 23.

Personal.—Dr. Edward S. Judd, Rochester, sustained painful burns on the face and hands from carbolic acid, June 15.——Dr. Arthur F. Kilbourne, superintendent of the Rochester State Hospital, was the guest of honor at a reception tendered him by the staff and employees of the hospital, June 11, on the occasion of the twenty-fifth anniversary of his connection with the institution as its superintendent. Dr. Kilbourne was presented with a gold watch, chain and masonic charm.——Dr. Justus Ohage assumed his duties as health officer of St. Paul, June 8.——Dr. Gustav A. Renz has been appointed assistant health officer of St. Paul.——Dr. Thomas Gratzek, St. Paul, has been appointed deputy coroner of Ramsay County.——Dr. Howard Lankester, retiring health officer of St. Paul, was presented with a gold-headed cane, and Assistant Health Officer Paul E. Cook with a leather traveling-bag by employees of the health department, June 1.——Dr. Carl J. Ringnell, wife and daughter, Minneapolis, and Dr. James W. Andrist, Owatonna, have started for Europe.

MISSOURI

County Helps in Tuberculosis Fight.—Buchanan County has authorized the appropriation of $2,500 to be expended by the Buchanan County Society for the Prevention of Tuberculosis for the purpose of carrying on its fight against this disease in the rural districts.

Personal.—Dr. George P. Pipkin, at present superintendent of the City Hospital, Kansas City, will assume charge of the Kansas City General Hospital, July 15, on the retirement of Dr. Rush E. Castelaw.——Dr. James B. Wright, Trenton, has started for Europe.

State Takes Over Sanatorium.—The recently completed infirmary building of the Missouri State Sanatorium for the Treatment of Incipient Tuberculosis, Mount Vernon, recently erected at a cost of $35,000, was formally turned over to the state by the contractors, June 6.

St. Louis

Invalid Home Opened.—The Jewish Home for Chronic Invalids and Consumptives of St. Louis, Fee-Fee Street, Anglum, Mo., was opened to receive patients, June 15. Mr. Louis Renard is president of the institution.

Personal.—Dr. Milton Schaic, formerly superintendent of the Montefiore Home and Sanatorium, Bedford Hills, N. Y., has been appointed medical director of the Jewish Home for Chronic Invalids and Consumptives, Anglum.

NEBRASKA

Personal.—Dr. Clarence B. Foltz, Omaha, who has been ill with scarlet fever, has recovered and resumed practice.——Dr. Fred A. Nelson, Omaha, was painfully injured in a collision between his automobile and a trolley-car, June 10.——Dr. and Mrs. August F. Jonas and Dr. Ernest W. Powell, Omaha, have started for Europe.

Medical Library Moves.—The directors of the Public Library of Omaha have been forced for lack of space to request the Douglas County Medical Society to remove their books, now housed in the Public Library. It is expected that arrangements will be made to provide a place near the business center of Omaha, where the books and publications may be available for reference.

NEW YORK

New Officers.—Jamestown Medical Society, June 10: president, Dr. Louis H. Snow; secretary-treasurer, Dr. William M. Sill, Bemus Point.——Medico-Chirurgical Society of Central New York, thirty-seventh annual meeting at Syracuse, June 4: president, Dr. Otis M. Wiley, Syracuse; secretary-treasurer, Dr. Earle A. Gayde, Utica (reelected).

Syracuse Alumni Meet.—At the annual meeting of the Medical Alumni of Syracuse University, held June 9, the annual address was delivered by Surgeon John F. Anderson, U. S. P. H. S., director of the hygienic laboratories, on "The United States Public Health Service; Its Origin; Its Work, and Its Accomplishments." Dr. Michael M. Lucid, Cortland, was elected president.

Personal.—Dr. Oliver W. H. Mitchell has received the permanent appointment as city bacteriologist of Syracuse.——Dr. Charles S. Allen, Rensselaer, gave a reception, June 8, in honor of his ninetieth birthday, which occurred two days before.——Dr. Otto Glogau, Syracuse, has sailed for Europe.——Dr. Wardner D. Ayer, Rensselaer, has succeeded Dr. J. W. Cox as pathologist of the Crouse-Irving Hospital, Syracuse.

State Hospital News.—Governor Glynn has vetoed the bill providing for the abandonment of the State Hospital at Mohansic and a companion bill appropriating $200,000 to begin a new state hospital at another point. This hospital, which is located within forty miles of New York City, on the city watershed, had considerable difficulty with the health authorities of New York City, but finally arranged to dispose of its sewage in a manner satisfactory to the city authorities. It is now hoped that the constructive work of this institution, which has thus been held back, will be permitted to continue.——The New York State Hospital Commission is now considering the purchase of a site comprising 162 acres at Oakside, L. I., for another state hospital. It is feared that opposition to the plan will be encountered on the part of wealthy residents of the neighborhood.

New York City

Cornell Commencement.—The annual commencement exercises of the Cornell University Medical College were held in the Dispensary Hall of the college building, June 11, at 4 p. m.

Hospital to Move.—The Volunteer Hospital, Gold Street, will move about July 1 into its new building on the corner of Water and Beekman Streets. The new building, four stories in height, will be able to accommodate fifty-five patients and has been erected at a cost of about $130,000.

Personal.—Dr. and Mrs. Henry L. Shively and Dr. and Mrs. Archibald M. Campbell have sailed for Europe.——Dr. L. Emmett Holt had conferred on him the degree of D.Sc. by Brown University, Providence, R. I., at its annual commencement, June 17.——Drs. Charles Wuest and George W. Long have been appointed coroner's physicians, vice Drs. Lester D. Volk and Gerard Kasper, resigned.

"Better Baby" Week.—From June 20 to 26 was Better Baby Week in Greater New York, the purpose of which was to plan for the greatest summer campaign yet waged in New York for the reduction of the death-rate among infants and young children. There were special meetings at all the infant welfare centers and 2,000,000 pieces of educational literature were distributed. The mayor has appointed commissions to supervise the work, among them being the Chamber of Commerce, the Merchants' Association, the Advertising Men's League, the Advisory Council of the Board of Health, the New York Board of Jewish Ministers, the Federation of Women's Clubs and the New York Conference on Charities. Mayor Mitchell has been appointed honorary president of the baby week. He has appointed Seth Low as president and eleven honorary vice-presidents have been appointed, together with a committee of fifty well-known citizens on whom will devolve the bulk of the work. In connection with the work of this week Mayor Mitchell has sent a letter to be read before all schoolchildren asking their cooperation in the baby-saving campaign and general instructions as to the care of the baby will be circulated among the schoolchildren.

PENNSYLVANIA

Commencement Week Clinic and Demonstrations.—From June 15 to 17 clinics were held at various hospitals of Pittsburgh by members of the faculty of the University of Pittsburgh School of Medicine and the various hospital staffs, for the benefit of the alumni of the institution, who had returned for commencement week.

Personal.—Dr. William K. Evans has been made chief of the new Health Department of Chester.——Dr. David S. Hollenbeck, the oldest practitioner in Shamokin, on the occasion of his seventy-first birthday, was presented with a gold-headed cane by the Medical Association of Shamokin.——Dr. James T. Macdonald, Bloomsburg, has gone abroad.

Philadelphia

Personal.—Dr. John L. Bower has sailed for Europe.——Dr. Edward A. Spitzkar has resigned as professor of anatomy in Jefferson Medical College.——Dr. John J. Gilbride has been elected assistant professor of surgery in the Medico-Chirurgical College.

Open-Air Clinics Begin.—The fifth season of the open-air clinics on the Chestnut Street pier began June 15. Dr. S. W. Newmayer has charge of the clinic, which is open between 8 a. m. and 5 p. m., the pier remaining open until 10 p. m.

Alumni Picnic.—The Alumni Society of the University of Pennsylvania held its annual celebration at Glenloch Park, N. J., June 4. The society also gave a smoker at the Alamac Hotel, Atlantic City, June 23.

Work of Alumnae.—At the thirty-ninth annual meeting of the Alumnae Association of the Women's Medical College of Pennsylvania, it was announced that a fellowship fund of $500 had been raised and awarded to Dr. Sarah L. Myers, Philadelphia, of the class of 1905; that the Hannah T. Croasdale fellowship now amounts to $1,800; that the Emma E. Musson Scholarship in otology amounts to nearly $700; and that the general endowment fund has almost reached $45,000.

Public Health Sunday.—Fifty-two pulpits of Philadelphia were occupied by members of the American Medical Association, June 21. Among the subjects discussed were the housing problem, milk supervision, segregation of consumptives, the social evil, elimination of occupational diseases, child labor, play grounds, the enactment of more stringent laws governing public health, the relation between morality and health, the prevention of sickness and the prolongation of life.

Medical Club Entertains.—A reception was given by the Medical Club of Philadelphia at the Bellevue-Stratford Hotel in honor of Dr. Victor C. Vaughan, Ann Arbor, President of the American Medical Association; Dr. Edward B. Heckel, Pittsburgh, president of the Medical Society of the State of Pennsylvania; Dr. Enoch Hollingshead, Pemberton, N. J., president of the Medical Society of New Jersey, and Dr. William P. Orr, Jr., Lewes, president of the Delaware State Medical Society. At the conclusion of the reception, Dr. James C. Wilson read a memoir of Dr. S. Weir Mitchell.

RHODE ISLAND

District Society Meeting.—The second annual meeting of the Woonsocket District Medical Society was held in Woonsocket, June 11. The following officers were elected: president, Dr. Joseph T. Roswell; vice-presidents, Drs. J. Edward Tanguay and Allen A. Weeden; secretary, Dr. Edward L. Myers, and treasurer, Dr. Robert G. Reed, all of Woonsocket.

State Society Meeting.—At the one hundred and second annual meeting of the Rhode Island Medical Society held in the Medical Library, Providence, June 4, the following officers were elected: president, Dr. Stephen A. Welch; vice-presidents, Drs. Frank L. Day and Edmund D. Cheesebro; secretary, Dr. Jay Perkins; treasurer, Dr. Winthrop A. Risk, all of Providence. The topic of the president's address was "Surgery of the Gall-Bladder and Biliary Tract." The next meeting of the society will be held in the State Tuberculosis Sanatorium at Wallum Lake, September 6.

SOUTH CAROLINA

New Sanitarium.—A permit has been issued to Drs. James W. Babcock and Eleanora B. Saunders to erect the Waverly Sanitarium, Columbia, to accommodate about 100 patients.

Tuberculosis Hospital to be Erected.—It has been decided to erect a tuberculosis hospital for which an appropriation of $10,000 was made by the last general assembly, on a site of about 70 acres in the State Park, provided the State Board of Health can obtain the consent of the Board of Regents of the State Hospitals for the Insane.

State Board Reelected.—At the meeting of the State Board of Health the following officers were unanimously reelected: president, Dr. Robert Wilson, Jr., Charleston; secretary and state health officer, Dr. James A. Hayne, Columbia; director of the laboratories, Dr. Francis A. Coward, Columbia, and director of rural sanitation, Dr. J. La Bruce Ward, Columbia.

State Red Cross Organized.—The South Carolina Red Cross Nursing Service Commission has been organized and is ready to receive applications for Red Cross nursing service. Applications may be made to Miss M. E. McKenna, the chairman, St. Francis Xavier Infirmary, Charleston, or to the secretary, Miss Agnes Watt, 2001 Assembly Street, Columbia.

Hospital Annex Opens.—The A. Markley Lee Memorial Annex to the Hospital and Training-School for Nurses, Charleston, the cornerstone of which was laid with appropriate ceremonies, December 15 last, has been opened to receive patients. The building is 18 by 60 feet, and two stories in height. The institution is in charge of the Charleston County Medical Association.

Personal.—Dr. Frank M. Durham, Columbia, is now in the Columbia Hospital suffering from knife and razor wounds of the side, cheek and thigh, received from a group of men who assaulted him, presumably with robbery as a motive.——Dr. Margaret L. E. Whiteside has been appointed second assistant physician at the State Hospital for the Insane, Columbia.——Dr. Angus B. Patterson, Barnwell, has been made physician in charge of the branch of the State Hospital, soon to be erected in the State Park.

WISCONSIN

Eye, Ear, Nose and Throat Specialists to Meet.—The first annual meeting of the Wisconsin Eye, Ear, Nose and Throat Specialists will be held at Oshkosh, October 8.

New Sanatorium.—Dr. Samuel B. Ackley, for several years a member of the staff of the Caples Sanatorium, Waukesha, has leased the Rosencranz property on Lac La Belle, Oconomowoc, for a sanatorium.

Personal.—Dr. W. Weber Kelly, Green Bay, Drs. Niel Andrews, Jr., Clarendon Coombs and F. Gregory Connell, Oshkosh, have started for Europe.——Dr. C. C. Crawley, Grand Rapids, has been appointed assistant physician to the Oshkosh State Hospital.

Leper to Remain at Soldiers' Home.—Bernard D. Bennett, who was found to be suffering from leprosy while an inmate of the National Soldiers' Home, near Milwaukee, has been isolated, and is being cared for by another inmate of the home in a house on the grounds of the home.

GENERAL

Travel Tour Abandoned.—The American Association for Physicians' Study Travels has abandoned its tour for this year on account of the magnitude of the proposed trip for 1915. At the meeting of the society in Atlantic City, June 25, the itinerary for next year was discussed.

Millions for Medical School.—By the will of James Campbell of St. Louis, the entire estate, valued at $40,000,000, is eventually devised to the St. Louis University for the establishment and endowment of a medical school and hospital. During the life of his wife and only daughter they will share equally the income of the state. Twenty-one years after the death of the legatees, the entire estate is to go to the university.

Orthopedists Hold Annual Meeting.—The twenty-eighth annual meeting of the American Orthopedic Association was held June 18-20, under the presidency of Dr. Gwilyn C. Davis; clinics being held on the seventeenth. The following officers were elected: president, Dr. George B. Packard, Denver; vice-presidents, Drs. Jefferson D. Griffith, Kansas City, Mo., and William S. Baer, Baltimore; secretary, Dr. Ralph R. Fitch, Rochester, N. Y., and treasurer, Dr. John L. Porter, Chicago.

Personal.—The degree of LL.D. was conferred by Yale University at its two hundred and fourteenth annual commencement exercises on Surg.-Gen. William Crawford Gorgas.——The honorary degree of Ph.D. was conferred on Surgeon-General Gorgas by Princeton University at its one hundred and sixty-seventh annual commencement exercises, June 16.——Dr. John S. B. Pratt, president of the Territorial Board of Health, Honolulu, has reached San Francisco on his way to Washington to protest against the sending of John Early, the leper who recently escaped and was found in Washington, to the Molokai Leprosarium.

Error in Statement Regarding Death of Goldberger.—In The Journal last week in an editorial "The Transmission of Typhus Fever," page 1966, the statement is made "that most of the recent advances in our knowledge of this once dreaded disease have been due to the work of American investigators, although the toll through the loss of life of two of the investigators—Ricketts and Goldberger—has been severe." Dr. Goldberger is still active in the United States Public Health Service. The investigator who died was a coworker, James Francis Conneffe, who succumbed at the age of 33 from typhus fever contracted while investigating the disease.

Climatologists Meet.—The thirty-first annual meeting of the American Climatological Association was held in Atlantic City, June 20, under the presidency of Dr. James M. Anders, Philadelphia. The following officers were elected: president, Dr. Henry Sewall, Denver; vice-presidents, Drs. Arthur K. Stone, Boston, and J. Alexander Miller, New York City; and secretary-treasurer, Dr. Guy Hinsdale, Hot Springs, Va. (reelected). Dr. James M. Anders, Philadelphia, was elected a member of the council, and Dr. Thomas Darlington, New York City, a representative on the executive committee of the Congress of American Physicians and Surgeons. The association will hold its next meeting at San Francisco in 1915.

Bequests and Donations.—The following bequests and donations have recently been announced:

Deaconess Hospital, Peoria, Ill., one-third of an estate of $38,000, by the will of Dr. George McPherson, Tonica, Ill.

New York Skin and Cancer Hospital, $25,000; Society for the Relief of Wives and Children of Medical Men; Children's Aid Society, and Association for Improving the Condition of the Poor, each $10,000, by the will of Dr. Everett Herrick.

Presbyterian Hospital, St. Luke's Hospital, and New York Post-Graduate Medical School and Hospital, each $100,000 by the will of Harris C. Fahnestock.

Johns Hopkins Medical School, a donation of $1,500,000 from the Rockefeller General Education Board, to establish the William H. Welch endowment for clinical education and research.

New York University, a trust fund of $10,000 by the will of Dr. Joseph D. Bryant which is to be "devoted to the instilling in the minds of the senior classes the principles of ethics of the American Medical Association. This bequest is made in the belief that early admonition and planting of preventive means against seductive inclinations and dangers is the surest method of insuring ethical practice in human affairs."

Norwich, New York, Hospital; New York Academy of Medicine, and New York University, each one-seventh of the residuary estate of Dr. Joseph D. Bryant, after the death or remarriage of Mrs. Bryant.

St. Vincent's Hospital, New York City; American Medical Association; Bellevue Hospital Alumni Association Medical Society of New York, and other institutions, equal parts of the daughter's share of the residuary estate of Dr. Bryant, provided the daughter dies before Mrs. Bryant.

A contingent bequest of $10,000 by the will of Dr. Bryant to oppose the antivivisectionists of the State.

Presbyterian Hospital and Philadelphia Home for Incurables, portions of the residuary estate of Mary Ford, valued at $18,000.

St. Joseph's Hospital, Philadelphia, a donation of $5,000 by George W. Nevil, for the endowment of a free bed in memory of Joseph and Amelia Nevil.

Presbyterian Hospital, Philadelphia, $1,000, by the will of Annie E. Claghorne.

To a hospital in Philadelphia, a contingent bequest of $5,000 under the will of Elizabeth Collins. The residue of the estate is devised to the Home of the Merciful Saviour for Crippled Children, on condition that the institution use two buildings at Sea Isle City for the inmates of the Home. If this request is denied, the money is to be divided between the Presbyterian Hospital and the Episcopal Hospital for free beds.

FOREIGN

Not Plague but Pneumonia.—The mysterious and suspicious disease which appeared at Colombian ports, near the Isthmus of Panama, and which it was feared was bubonic plague, has been investigated by Dr. Samuel T. Darling, chief of the Ancon Hospital, and found to be pneumonia.

Prize Awarded to Julliard.—Prof. C. Julliard of Geneva, Switzerland, was awarded the prize founded by the International Congress for Industrial Accidents at Rome in 1909. His subject was "The Functional Adaptability of Limbs Injured in Industrial Accidents and Means to Increase It."

Wellcome Historical Museum Opened.—The historical medical museum of Henry S. Wellcome, on the occasion of the seventeenth International Congress of Medicine, was reopened May 28 as a permanent institution, now known as the Wellcome Historical Medical Museum, and will be open daily from 10 a. m. to 6 p. m. at 54a Wigmore Street, Cavendish, London, England. Members of the medical and kindred professions are admitted on the presentation of their professional cards.

LONDON LETTER

London, June 5, 1914.

The New Edition of the British Pharmacopeia

The last edition of the British Pharmacopeia was published in 1898, and 46,081 copies and 4,525 copies of the Indian and Colonial Addendum have been sold. The work of preparing a new edition has now been completed. One of the chief features will be that limits of impurity in drugs and medicinal chemicals—especially dangerous impurity—will be carefully defined. For instance, at present potassium carbonate containing arsenic will pass the test of the Pharmacopeia of 1898, but it will not pass the 1914 edition, which will limit the quantity to two parts per million. Again, in regard to lead contamination in tartaric acid—the importance of which has been recognized both by the government and by the local authorities—the limit of admixture is prescribed as ten parts per million as compared with a very indefinite limitation before. Another feature of the book is an extension of chemical standardization to drugs not at present standardized, but there is no recognition of physiologic standardization. Notwithstanding the advances that have been made in physiologic methods of testing the strength of drugs—especially of those drugs which do not admit of chemical standardization—it has been felt that the time is not yet ripe and knowledge not sufficiently perfect to adopt animal tests in this edition. The international unification of the quality of preparations of potent drugs, notably those of henbane, belladonna, aconite, nux vomica, etc., has received the endorsement of various nations through a Hague conference, and has due recognition in the forthcoming book, so that a person having the same prescription made up in, say, London, Brussels and Paris, will obtain a preparation of uniform strength.

Penal Cases before the General Medical Council: Physicians' Certificates

The General Medical Council is a body consisting of physicians appointed to supervise medical education and to investigate and adjudicate on charges made against physicians in their professional capacity. It is, in fact, a professional court of law. The penal cases which come before it are often of a painful nature and result in the severest sentence it can pronounce—the removal of a physician's name from the register. This does not prevent the physician from practicing, for in this country it is not illegal for even an unqualified person to practice, though he does so with the liability to be tried for manslaughter in case of the death of a patient. Removal from the register deprives a physician of all his professional privileges. He cannot sign a death certificate, and should a patient attended by him die an inquest will therefore become necessary. Further, he cannot sue for the recovery of fees. In the giving of medical certificates, cases of laxity occur from time to time. The council has recently issued a warning to physicians on the subject. The following cases have just come before it:

A physician was convicted of making a false declaration on a death certificate at a police court. A young woman died in a nursing home and he gave a certificate in which the primary cause of death was stated to be appendicitis and the secondary peritonitis. He was aware that while in the home she had a miscarriage. He had been asked by the patient not to inform her sister of her condition. The accused physician said that the certificate had been filled in with the omission of the word "miscarriage" without any improper motive or intention to deceive. He did so to save the girl's honor, having promised not to divulge. The council took the gravest view of the case, but having regard to the punishment which the physician had previously received (the payment of a fine and damages to the amount of $100), decided to suspend judgment until November, when the physician would be required to produce evidence that his conduct had been without reproach in the interval.

The following case terminated more seriously for the accused: A physician at the request of an insurance agent filled in and signed death certificates for seven persons, none of whom he had attended and all of whom were present at his trial. The insurance agent was thus able fraudulently to obtain the sums for which they were insured. In defense the physician said that he had been induced to sign the certificates by the insurance agent in whom every one in the town had confidence. When he asked as to the legality of the procedure he was told that it was a matter of form with the insurance company and that another physician had been doing it for years. The council directed that the physician's name should be removed from the register.

BERLIN LETTER

Berlin, May 29, 1914.

Personal

A few days ago Prof. Max Wolff of Berlin celebrated his seventieth birthday. For some years he has been the head of the University clinic for pulmonary diseases, and in this capacity has repeatedly published the results of his experiences with new remedies which have been recommended for pulmonary tuberculosis.

Tuczek, professor of psychiatry at Marburg, and G. Schwalbe, the anthropologist of the University of Strassburg, retire at the end of the summer semester in consequence of their advanced age.

Dr. Schlossberger has been appointed as head of a department in the Institute for Hygiene and Experimental Therapy at Marburg in place of Römer, who has been transferred to Greifswald as professor of hygiene.

G. Klemperer has resigned his position as chief of the cancer institute of the Charité in Berlin. No notable results have been achieved by the institute during his term of office, although he has had the private advice of the chemist of our university, Prof. Emil Fischer.

TRENDELENBURG'S SEVENTIETH BIRTHDAY

Friedrich Trendelenburg, the former director of the surgical clinic of Leipsic, celebrated his seventieth birthday, May 24. A former pupil of Langenbeck, Trendelenburg stands in the front rank of those surgeons who were pioneers at the beginning of the antiseptic era of surgery, and to whom German surgery owes its acknowledged position. Among the numerous important articles of Trendelenburg we can notice only his studies in the field of joint and bone surgery, gastrostomy for stricture of the esophagus, tracheotomy, the practice of raising the pelvis for operations—first recommended by him—and his articles on operations on the bladder and on the treatment of varicose veins. Trendelenburg was an excellent teacher and so far the worthy successor of Thiersch. Moreover with reference to his personal qualities, Trendelenburg, who resigned his position some years ago, still enjoys the greatest respect and general affection.

Friedmann's Remedy

The unfavorable publications which have appeared in the *Deutsche medizinische Wochenschrift* have been followed in the last few weeks by other articles of the same tenor. The Berlin surgeon Karewski reported his results at a meeting of the Berlin Medical Society, stating that he had obtained no improvement worth mentioning, but had to report various undesired side-actions. The discussion, in which a number of specialists took part, followed in general the same lines. In the last number of the *Münchener medizinische Wochenschrift,* Schittenhelm, director of the university medical clinic at Königsberg, has an article in which he comes to the conclusion that the objectionable accompanying actions of the remedy compel him to abandon further trials of it. (Summaries have appeared in the Current Literature Department.)

New Institute for Tropical Diseases

A new institute for ship and tropical diseases was dedicated at Hamburg, May 28. The new building consists of three parts, an administration building, a hospital and an animal house.

The Death-Rate of Prussia for 1912

The great mortality of 1911 (17.2 per thousand) in Prussia, which was occasioned by the high infant death-rate of the hot summer, fortunately was reduced in 1912 by 60,511 persons, and is more favorable than that of the year 1910 by 1,679. If the mortality-rate is calculated without including the still-births, the figure for 1,000 persons living July 1, 1912, is 15.5, the lowest ever recorded. Going back to 1875, we find the highest death-rate, 26.3.

Marriages

Joseph Henry Shuffleton, M.D., Kings Park, N. Y., to Miss Elsie Nelson Henschel of Northport, L. I., N. Y., June 24.

John Henry Noonan, M.D., Belgrade, Mont., to Miss Edith Harper of Salt Lake City, at Bozeman, Mont., June 1.

Clarke Campbell Patton, M.D., Vermilion, S. Dak., to Miss Anna Marie Kellogg of Ashland, Ohio, May 28.

Raymond Fox Roller, M.D., Galesburg, Kan., to Miss Fern Mae Green of North Manchester, Ind., May 26.

Edward C. Spitze, M.D., East St. Louis, Ill., to Miss Esther Louise Niedermeyer of Decatur, Ill., June 17.

Arthur Narcisse Chatel, M.D., Laurium, Mich., to Miss Marie Elinor McDermott of Kewanee, Ill., June 2.

Orval James Cunningham, M.D., Kansas City, Mo., to Miss Grace Margaret Quinlan of Chicago, June 7.

Alfred Thomas Sheffield, M.D., Holland, Va., to Miss Stella Eloise Smith of Portsmouth, Va., June 25.

Roy Bertrand Harrison, M.D., New Orleans, to Miss Maccie Martha Haas of Alexandria, La., June 3.

Thomas Lynch Cooksey, M.D., Crawfordsville, Ind., to Miss Minnie Beattey of Hico, Tex., February 24.

Wenceslaus James Kavan, M.D., Bee, Neb., to Miss Olie Kolarik of Crete, Neb., at Wilbur, Neb., June 1.

Robert Kendig Rewalt, M.D., Middletown, Pa., to Miss Mary H. Cochran of Williamsport Pa., June 3.

John Augustine Daly, M.D., Andover, Mass., to Miss Mary Agnes O'Brien of Lowell, Mass., June 10.

George Leon Bastian, M.D., to Miss Katherine Smith Winegar, both of Manchester, N. H., June 11.

Francis James Conroy, M.D., Sterling, Ill., to Miss Blanche Murrin of Rock Island, Ill., June 2.

Stephen D. Large, M.D., Hopkins, Mo., to Miss Susan Lawrence of St. Joseph, Mo., June 10.

Adrian Benton Perkey, M.D., Los Angeles, Cal., to Miss Susie B. Ford of Chicago, June 4.

Harlan Lloyd Paine, M.D., Hathorne, Mass., to Miss Amy Yeo of Salem, Mass., June 10.

Louis Feid, Jr., M.D., Cincinnati, Ohio, to Miss Elizabeth Knight of Madeira, Ohio, June 10.

John Mathew Lilly, M.D., to Miss Mary Charlotte Seitsinger, both of Chicago, June 16.

Simeon Burt Wolbach, M.D., to Miss Anna Wellington, both of Boston, Mass., June 10.

Harold Colton Herrick, M.D., to Miss Daisy Johnson, both of St. Louis, June 9.

Cleaver Henry Brinkerhoff, M.D., to Miss Clara Wagner, both of Chicago, June 10.

J. Earl McIntyre, M.D., to Miss Sadie Barclay of Menominee, Mich., June 17.

John Fulton Roe, M.D., to Miss Lee Howard, both of Denver, Colo., June 10.

Howard R. Weirick, M.D., to Miss Marilla Beaty, both of Hibbing, Minn., June 5.

George Dohrmann, M.D., to Miss Kaethe Heinsohn, both of Chicago, June 12.

Deaths

George Frederick Reinhardt, M.D. University of California, San Francisco, 1900; aged 45; a Fellow of the American Medical Association; and formerly president of the State Board of Medical Examiners of California; professor of hygiene in the University of California since 1904; and founder of the self-supporting college infirmary system; died in the infirmary of the University of California, Berkeley, June 7, from an infection of the lungs, resulting from a carbuncle.

George Perley Bradley, M.D. College of Physicians and Surgeons in the City of New York, 1870; a Fellow of the American Medical Association and a member of the Association of Military Surgeons of the United States; who entered the United States Navy in 1870, and was retired for incapacity resulting from an incident of service in 1907 as medical director, with the rank of captain; died at his home in South Lancaster, Mass., June 14, aged 65.

Otto Gustaf Ramsey, M.D. University of Virginia, Charlottesville, 1890; of New Haven; a Fellow of the American Medical Association; and professor of obstetrics and gynecology in Yale University Medical School for fifteen years; who was given the honorary degree of M.A. by Yale University in 1901; died in a hospital in New Haven, June 12, from pneumonia, aged 44.

Sidney H. Gardiner, M.D. Queen's University, Kingston, Ont., 1889; a Fellow of the American Medical Association; and a surgeon of great initiative and skill, who devised the aluminum splint, which is at present in use in the U. S. Navy; died in his private surgical sanatorium in Brooklyn, June 10, eighteen days after an operation for appendicitis, aged 51.

Benjamin Franklin Oswald, M.D. Western Reserve University, Cleveland, Ohio, 1894; a member of the Ohio State Medical Association; of Lakewood, Ohio; stepped from a car in Cleveland, June 10, and was struck by an automobile, sustaining injuries from which he died at St. Alexis' Hospital an hour later, aged 50.

Joseph W. Shellfish, M.D. Michigan College of Medicine and Surgery, Detroit, 1895; a Fellow of the American Medical Association; lecturer on materia medica and anesthesia, and clinical assistant to the chair of practice in his Alma Mater; died at his home in Detroit, June 8, from valvular heart disease, aged 40.

Henry A. Dinges, M.D. Missouri Medical College, St. Louis, 1886; a Fellow of the American Medical Association; thrice mayor of Red Bud, Ill.; and local surgeon of the Mobile and Ohio Railroad; Supreme Physician of the Catholic Knights of America; died at his home in Ruma, Ill., May 30, aged 59.

William Jasper Wilhite, M.D. College of Physicians and Surgeons, Keokuk, Ia.; a surgeon in the Confederate service during the Civil War; and one of the board of insanity commissioners for Stanislaus County, Cal.; died at his home in Modesto, Cal., May 31, from senile debility, aged 77.

Frank Albert Shaver, M.D. University of Michigan, Ann Arbor, 1903; a Fellow of the American Medical Association; and for a year thereafter assistant physician in the Kalamazoo State Hospital; died at his home in Grindstone City, Mich., May 29, from nephritis, aged 40.

William Charles Bunce, M.D. Wooster University, Cleveland, Ohio, 1878; a Fellow of the American Medical Association; chief surgeon of the Cleveland, Southwestern and Columbus Railway; died at his home in Oberlin, June 9, from valvular heart disease, aged 56.

Charles Jenks Simons, M.D. Albany (N. Y.) Medical College, 1867; a member of the Illinois State Medical Society, and a veteran of the Civil War; a practitioner of Chicago since 1868; died at his home in Chicago, June 18, from arteriosclerosis, aged 71.

Jacob J. Fulkerson, M.D. Washington University, St. Louis, 1875; a member of the Missouri State Medical Association; a Confederate and Spanish-American War veteran; died at his home in Lexington, Mo., June 6, from cerebral hemorrhage, aged 65.

Samuel Casper Ermentrout, M.D. University of Pennsylvania, Philadelphia, 1866; a member of the Medical Society of the State of Pennsylvania, and the Pennsylvania Pharmaceutical Society; died at his home in Reading, Pa., April 20, aged 70.

D. W. Patton, M.D. Dearborn Medical College, Chicago, 1905; inspector of meats in the federal service; for several years a resident of North Dakota; while on his way to Omaha to resume his official position, was killed in an automobile accident at St. Joseph, Mo., June 3, aged 45.

Emil Gamson, M.D. Medico-Chirurgical College of Philadelphia, 1898; a Fellow of the American Medical Association; and for fifteen years a practitioner of Bayonne, N.J.; died in Brooklyn, N.Y., May 30, from lymphosarcoma of the neck and thorax, aged 42.

Alexander B. Duncan, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1868; formerly Representative of Lee County, Ga., in the State Legislature and a practitioner of Leesburg; later a resident of Atlanta; died in Leesburg, May 29, aged 76.

William Jefferson Walker, M.D. University of Pennsylvania, Philadelphia, 1887; a member of the Medical Society of the State of Pennsylvania; and for many years a resident of Homestead, Pa.; died in Springfield, Ohio, recently.

Elliott E. Furney, M.D. Missouri Medical College, St. Louis, 1875; a Fellow of the American Medical Association, and for many years a practitioner of St. Louis; died recently at his home in St. Petersburg, Fla., aged 66.

Stephen D. Hughes, M.D. College of Physicians and Surgeons, Memphis, Tenn., 1908; of Wilmar, Ark.; formerly a member of the Arkansas State Board of Health; died in a hospital in Little Rock, June 1, aged 43.

O. B. Webster, M.D. University of Buffalo, N. Y., about 1848; for fifty years a practitioner of Lansing, Mich.; died at the home of his grandson in Vassar, Mich., April 30, from senile debility, aged 87.

Israel Goodrich Sims, M.D. Miami Medical College, Cincinnati, 1874; a member of the Indiana State Medical Association; died at his home in Portland, Ind., April 20, from cerebral hemorrhage, aged 69.

Adrian B. Coulter, M.D. Hahnemann Medical College, Chicago, 1867; surgeon of U. S. Volunteers during the Civil War; for many years an optician of Chicago; died at his home, June 10, aged 74.

William H. Searles, M.D. Chicago Medical College, 1865; of Oshkosh, Wis.; a specialist on diseases of the eye, ear, nose and throat; died at his home in Oshkosh, June 4, from heart disease, aged 74.

Royal Lacey Higgins, M.D. Bellevue Hospital Medical College, 1867; of Norwalk, Conn.; a member of the Connecticut State Medical Society; died in Bridgeport, Conn., April 16, aged 72.

Claude A. Stonecipher, M.D. Baltimore Medical College, 1904; formerly demonstrator of anatomy in his Alma Mater; died in the House of Correction, Baltimore, May 30, from nephritis, aged 33.

Willard C. Dickens, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1890; a member of the Wisconsin State Medical Society; died at his home in Wausau, Wis., May 31, aged 57.

Thaddeus Joseph Dean (license, Washington, 1905) Surgeon of U. S. Volunteers during the Civil War; a practitioner for fifty-five years; died at his home in Seattle, May 23, aged 77.

Ezra New, M.D. Medical College of Georgia, Augusta, 1887; a member of the Medical Association of Georgia; died at his home in Dublin, Ga., June 4, from angina pectoris, aged 54.

Thomas R. Bruce, M.D. University of Michigan, Ann Arbor, 1856; for more than thirty-two years a resident of Festus, Mo.; died at his home, May 28, aged 90.

Ezmon W. Earle, M.D. Pulte Medical College, Cincinnati, 1877; of Rochester, N. Y.; died in the Hahnemann Hospital in that city, June 4.

Simeon David Bateman, M.D. New Orleans, about 1855; died at his home in Newport, Ark., March 29, from senile debility, aged 87.

Jesse Blackburn Mickle, M.D. Eclectic Medical Institute, Cincinnati, 1891; died at his home in Erie, Pa., about June 2, aged 54.

Emil Knese, M.D. University of Wurzburg, Germany, 1873; died at his home in Cincinnati, June 2, from nephritis, aged 67.

Nathaniel Brown Rice, M.D. Albany, N.Y., Medical College, 1854; died at his home in Chicago, June 10, aged 84.

Miscellany

Prophylactic Use of Quinin in Malaria

Surgeon H. R. Carter, in a recent issue of *Public Health Reports*, thus summarizes the results of his study of this question:

The use of quinin in small doses is an efficient method for preventing malarial fever.

This method is especially adapted for use in a farming community where it is not practicable economically to get rid of malarial mosquitoes or to properly screen against them.

In malarious states quinin should be taken in doses of from 5 to 7 grains per day by grown persons, 2 to 3 grains by children—less if small—during the malarial season, say, June to November. Somewhat smaller doses will be efficient in places where the malaria is not bad. If begun in March or April, it would prevent a certain number of relapses.

In these doses it does no injury and does not produce blackwater fever or cause malaria to be more difficult to cure by quinin.

It can be taken in these doses by almost all persons without discomfort, or with discomfort for only the first seven or eight days. In cases in which it does produce discomfort a smaller dose should be tried and, if possible, increased later.

The insoluble salts of quinin are better borne—that is, cause less discomfort—than the soluble. The tannate is the most insoluble and is said to be the best borne. Made up with chocolate and sugar into tabloids it is best suited for administration to children. As the tannate contains a smaller proportion of quinin than the sulphate, from two to two-and-a-half times as much must be taken to get the same effect.

In addition to the use of quinin, whenever it is practicable to do so, the house should be screened, brush and high weeds near it cut away and pools and wet places drained or filled. If the last is not practicable, wet places and pools should be oiled.

In a community using quinin prophylaxis there will still be a certain number of cases of malarial fever. Some of these will be failures of the method, but others, and the majority if it be used properly, will be relapses of previous malarial infections from the last season. In the Italian army in 1911 there were 304 relapses and 186 new cases to 10,000 men. A certain number of relapses are prevented by quinin prophylaxis, but not all.

The Surgery of the Ancients

A set of thirty-seven remarkable ancient Greek surgical instruments, discovered near the site of Kolophon, in Ionia, after being a considerable time in the possession of the late Mr. Alfred O. Van Lannep, Dutch vice-consul at Smyrna, has been brought to England. The instruments show a type of workmanship unequaled in any other extant specimens, and generally reveal the great progress in surgery which the ancients achieved. The date is probably the first or second century, A. D. With two exceptions, all the instruments are of bronze. The blades of the knives were originally of steel, but this metal has been almost completely destroyed by oxidation. Among the five pairs of forceps in the find is a large and beautifully made instrument, the handles of which are shaped to represent two dolphins. This is probably a pair of polypus forceps used for removing growths. The bite of the teeth is strong and close. Another interesting pair of forceps is that used for extracting arrow- and lance-heads from wounds. This pair somewhat closely resembles modern bone-forceps, and has artistically modeled handles and blades which possess strong teeth for gripping. An elevator for raising depressed bone is another interesting exhibit. The collection would seem to prove that after battle, efforts must have been made to treat surgically even the most serious wounds of the skull. Another brain instrument is the "drill-bow" for operating a skull trephine. This instrument proved a great puzzle at first, and was supposed to represent some sort of measuring appliance. Research, however, has shown that it is a bow which, when fitted in a string, was used to rotate a bone-drill or skull trephine. The British Museum possesses the only other specimen of the drill-bow extant, and until the discovery at Kolophon was made the nature of that instrument was not known. The collection includes tenacula similar to those now in use, a number of catheters of beautiful workmanship, shaped like modern instruments of the same type, a scoop or curet for gynecologic and other work (Hippocrates speaks of such an instrument), a cautery for burning wounds, a couple of probes exactly like the modern ones, a couple of spatulas or spoons, a needle-holder, and a bronze box intended evidently as an instrument case. In addition, there is a slab of Egyptian porphyry for mixing ointment on, and a well-constructed pair of scales, still in excellent equipoise. Some cupping-vessels were also discovered. This interesting collection of instruments has been given to the Johns Hopkins University and will shortly be taken to America. Models, however, are being made and will be on view in London.

Correspondence

Minnesota Regulations on Embalming-Fluid

To the Editor:—I am surprised that Dr. Jacob Rosenbloom should not have more fully informed himself on embalming-fluids now used throughout the country before writing his communication which was published in The Journal, June 13, 1914, p. 1912, and am rather surprised that in the comment on this communication, more attention was not given to the condition in Minnesota, the regulations of which state, as I understand it, have been used as a basis for the regulations in several other states.

There have been regulations governing the use of certain chemicals in embalming-fluids in the state of Minnesota for some time. The present regulation (No. 33), amending some of these older ones, reads as follows:

> After Sept. 1, 1909, every embalming-fluid sold or used in Minnesota must contain formaldehyd gas in the proportion of 5 per cent. by weight of the gas in every 100 parts by volume of the fluid, and must not contain any ingredient that interferes with the germicidal action of formaldehyd.
>
> *Such embalming-fluids must not contain chloral, nor shall they contain arsenic, mercury, zinc or other mineral poison.*

Regulation 34 reads as follows:

> After Sept. 1, 1909, a list of ingredients in every embalming-fluid sold or used in Minnesota must be on file in the office of the Minnesota State Board of Health.

These regulations have the force of law.

H. M. Bracken, M.D., St. Paul.
Executive Officer, Minnesota State Board of Health.

A Simple Method of Vaccination

To the Editor:—In The Journal, June 6, 1914, p. 1829, Dr. Shalet suggests that vaccination can be performed by dipping a sterile toothpick in glycerinated virus and abrading the arm by a rotary scarification. I have tried this method, with a sharp, chisel-shaped, hardwood toothpick, and have found it entirely satisfactory.

My serious objection to the original technic of Pirquet is the vaccination through the drop of lymph (or tuberculin). The whole point of our method is to make a circular scarification with a dry instrument on a dry skin. Then the toothpick is used to rub the virus (or tuberculin) into the abraded area. As skins are very different in thickness I find it much easier to judge the amount of pressure necessary to produce scarification if the skin and chisel are both dry. If lymph is dropped directly from a capillary tube on the scarified spots the chisel can be used for rubbing in the virus, thus eliminating the toothpick entirely. We use the toothpick because our virus comes to us in bulk and we wish to use the minimum quantity for each vaccination.

J. N. Force, M.D., Berkeley, Cal.
Assistant Professor of Epidemiology, University of California, Department of Hygiene.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

LIQUID PETROLATUM, LIQUID PARAFFIN, PARAFFIN OIL AND LIQUID ALBOLENE

To the Editor:—Kindly explain to me the exact difference between liquid albolene, liquid paraffin, paraffin oil and liquid petrolatum.

B. F. Newlon, M.D., Ponca City, Okla.

Answer.—In a general way the four products mentioned in your inquiry are alike. All of them could be included under the title "liquid petrolatum" as this title is used in the United States Pharmacopeia.

Liquid paraffin is the name used in the British Pharmacopeia for a liquid petrolatum, the specific gravity, however, being limited to a range of from 0.885 to 0.890; while the United States Pharmacopeia states that liquid petrolatum may have a specific gravity varying from 0.87 to 0.94 at 25 C. (77 F.).

Paraffin oil is not recognized as a title in either the British or the United States Pharmacopeia. It is used, as we understand, in about the same sense as liquid petrolatum.

Liquid Albolene is a light variety of liquid petrolatum marketed as a proprietary medicine exploited in an objectionable manner and with more or less misleading claims. Both liquid paraffin and Liquid Albolene are varieties of liquid petrolatum which are said to come from Russia, and differ from American products by being entirely non-fluorescent—an immaterial difference. See full discussion of this subject in The Journal, May 30, 1914, p. 1740.

REFERENCES TO POISONING BY METALLIC COOKING-UTENSILS

To the Editor:—Please tell me where I may obtain information concerning poisoning from copper and tin cooking-utensils.

E. H. S., Mt. Morris, Ill.

Answer.—The following is a list of references to articles on this subject:

CORPUS LUTEUM FROM PREGNANT COWS

To the Editor:—From what firms can one obtain corpus luteum extracted from the ovaries of pregnant cows?

J. Z. Mraz, M.D., Prague, Okla.

Answer.—We are unaware that any firms make a distinction in the character of ovaries from which they remove the corpora lutea. As, however, the investigations of McCord (The Journal, April 18, 1914, p. 1250) show that a very large majority of the cows from which corpora lutea could be readily removed were pregnant, the probability is that a high percentage of the corpus luteum offered for sale is derived from pregnant cows. The only firm offering corpus luteum from cows as far as we know is Armour. See New and Nonofficial Remedies, 1914, page 183.

HYPOPHOSPHITES IN TUBERCULOSIS

To the Editor:—Kindly advise me whether or not Winchester's Hypophosphites, which is prescribed by some doctors in the treatment of tuberculosis, is of any real value.

C. W. Miller, Denver.

Answer.—No. It is now agreed that the hypophosphites pass through the system unchanged; they certainly have no specific influence when used in the treatment of tuberculosis.

TREATMENT IN TYPHOID

To the Editor:—Please answer the following questions:

1. Is it good practice to keep an ice-bag on the abdomen of a typhoid patient from the beginning of the sickness until the very last? Is it good practice to put an ice-bag on the abdomen of a typhoid patient at any time of the sickness, when neither hemorrhage nor perforation is threatened?

2. Is it good practice to give a typhoid patient crackers, toast, and a certain amount of sweets? Would such a diet elevate the temperature of the patient and could it produce serious results?

Leon J. Menville, M.D., Houma, La.

Answer.—1. An ice-bag should not be employed unless some positive indications for its use exist, such as hemorrhage, orchitis or other inflammatory complication.

2. A diet containing crackers, toast and sweets is approved by many clinicians. There is no likelihood that it would do harm.

ARTICLES ON RECTAL ETHERIZATION

To the Editor:—Please give me the details of rectal ether anesthesia or refer me to recent works on the subject.

Howard M. Clute, M.D., Hanover, N. H.

Answer.—The following are references to recent studies on this subject:

Coburn, R. C.: Increase in Toxication of Ether by New Methods of Administration, The Journal, Jan. 31, 1914, p. 364.
Gwathmey, J. T.: Oil-Ether Anesthesia, *New York Med. Jour.*, Dec. 6, 1913, and Jan. 31, 1914; abstr., The Journal, Dec. 20, 1913, p. 2274.

Rectal Anesthesia, Therapeutics, The Journal, Dec. 16, 1911, p. 1997.
Arnd, K.: General Ether Anesthesia by the Rectum, *Arch. f. klin. Chir.*, xcv, No. 1.

ENLARGEMENT ON LIP IN SYPHILIS

To the Editor:—1. On the septum of the upper lip of a large proportion of syphilitic patients there is a small enlargement varying in size from a pin-head to a small pea. Is this a syphilitic glandular enlargement, or what is its significance?

2. Can you refer me to any literature on the subject? O. D. P.

Answer.—1. We know of no such symptom as a regular occurrence in syphilis. A small lymphatic node in this location may become enlarged and palpable, but cases have not been common.

2. We have been unable to find any literature on this specific subject.

INSTITUTION FOR BACKWARD CHILDREN

To the Editor:—I am very desirous of placing my boy in a good school for backward children in some part of the South, and ask if you can give me the address of such a school. The boy is now in a school of that kind near Philadelphia, but I prefer to have him nearer home, and in a milder climate. I do not know that first-class schools for that class of children really exist in the South, but if they do, I shall be glad for you to furnish me the address of two or three of the best.

X. Y. Z.

Answer.—We shall be glad to receive addresses of such institutions in the South to forward.

McClintic's Work on Rocky Mountain Spotted Fever.—In *Public Health Reports*, April 24, 1914, Surgeon L. B. Fricks reviews the work of Dr. T. B. McClintic on Rocky Mountain spotted fever in Montana. Dr. McClintic carried on his second series of investigations of Rocky Mountain spotted fever in the Bitter Root Valley during the summer of 1912. Just at the close of a successful season's work, he contracted the disease and died. Because of the importance of the work his notes have been carefully arranged, tabulated and amplified by explanations of the methods of procedure. There is a summary of the results obtained. The report covers the portion of the work relating to the collection of ticks, the determination of those infected by animal experimentation, and the examination of ground-squirrels, woodchucks and other small animals.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 14. Chairman, Dr. W. H. Sanders, Montgomery.

Alaska: Juneau, July 7. Sec., Dr. Henry C. De Vighne, Juneau.

Arizona: Phoenix, July 7-8. Sec., Dr. John Wix Thomas, Phoenix.

Colorado: Denver, July 7. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, July 14-15. Sec., Dr. Chas. A. Tuttle, New Haven. Homeopathic: New Haven, July 14. Sec., Dr. Edwin C. M. Hall, New Haven. Eclectic: New Haven, July 14. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

Indiana: Indianapolis, July 14-16. Sec., Dr. W. T. Gott, State House, Indianapolis.

Maine: Augusta, July 7-8. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Massachusetts: Boston, July 14-16. Sec., Dr. Walter P. Bowers, Room 159 State House, Boston.

Montana: Helena, June 30-July 2. Sec., Dr. Wm. C. Riddell, Helena.

New Hampshire: Concord, July 1-2. Regent, Mr. H. C. Morrison, Concord.

New Mexico: Santa Fe, July 13. Sec., Dr. W. E. Kaser, East Las Vegas.

North Dakota: Grand Forks, July 7. Sec., Dr. G. M. Williamson, Grand Forks.

Oklahoma: Oklahoma City, July 14. Sec., Dr. John W. Duke, Guthrie.

Oregon: Portland, July 7-9. Sec., Dr. L. H. Hamilton, Medical Bldg., Portland.

Rhode Island: Providence, July 2-3. Sec., Dr. Gardner T. Swarts, State House, Providence.

South Dakota: Deadwood, July 14. Sec., Dr. Park B. Jenkins, Waubay.

Utah: Salt Lake City, July 6-7. Sec., G. F. Harding, 405 Templeton Bldg., Salt Lake City.

Vermont: Burlington, July 14-17. Sec., Dr. W. Scott Nay, Underhill.

Washington: Seattle, July 7. Sec., Dr. C. N. Suttner, Baker Bldg., Walla Walla.

West Virginia: Elkins, July 1. Sec., Dr. S. L. Jepson, Wheeling.

Wisconsin: Milwaukee, June 29. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

Wyoming: Laramie, July 9-11. Sec., Dr. H. E. McCollum, Laramie.

Oregon January Report

Dr. L. H. Hamilton, secretary of the Oregon State Board of Medical Examiners, reports the written examination held at Portland, Jan. 6-8, 1914. The number of subjects examined in was 15; total number of questions asked, 108; percentage required to pass, 75. The total number of candidates examined was 75, including 1 osteopath and 31 non-graduates, of whom 42 passed, including 1 osteopath and 13 non-graduates, and 33 failed, including 18 non-graduates. The following colleges were represented:

PASSED

The following questions were asked:

PHYSIOLOGY

1. Mention three forms of contractile tissue found in the body. 2. Define central nervous system, sense organ, reflex action and inhibition. 3. Trace the afferent and efferent nerve impulses in colic of the colon. 4. Mention five functions of the blood. What is the source of the red blood-corpuscles? 5. Mention two structures of the body in which glycogen is stored. Into what is it changed for solution in the blood? 6. Mention the different gases found in arterial blood. Give the percentages of each. 7. State the percentage of water in the human body. In blood. In muscle. In bone. 8. Describe the digestion and absorption of fats.

NERVOUS DISEASES

1. Describe the symptoms, general and local, of a tumor occupying the lower half of the convolution in front of the fissure of Rolando on the left side. 2. Describe and locate the principal lesion in locomotor ataxia. Differentiate locomotor ataxia symptomatically from primary lateral sclerosis. 3. Name four cases of multiple neuritis. Describe the development and symptoms of postdiphtheritic multiple neuritis. 4. Give the etiology and symptomatology of chorea.

MATERIA-MEDICA AND THERAPEUTICS

1. What is apomorphin? Give its dose and physiologic action. 2. Name the most important preparations of bismuth. Give therapeutic uses. What dangers are connected with its use? How avoided? 3. Give indications for the use of arsenic compounds. Name the most important preparations with doses. 4. Give the strength of solution of nitrate of silver for use in eye, bladder and throat. What effect is produced by long continued use in the eye? 5. Compare action of atropia with adrenalin. 6. Name one drug each to be used against tapeworm, roundworm and hookworm. Give preparation, dose and danger of each. 7. Discuss indications for the local use of carbolic acid. What precautions are to be observed? 8. What is the active substance in thyroid gland? Give physiologic action, indications and contra-indications.

GYNECOLOGY

1. Give technic of bimanual examination. What do you find in the fornices of the vagina? 2. With what conditions may vaginal hernia be confused? 3. Give causes and pathologic changes in senile endometritis. 4. Define subinvolution of the uterus and give symptoms. 5. Name four varieties of ovarian cyst and describe the glandular variety. 6. What are the causes of ectopic gestation? Give symptoms before, during and after rupture. 7. Give general effects of double salpingo-oophorectomy. 8. Describe a tuberculous infection of any one of the female organs.

DIAGNOSIS

1. Differentiate bronchiectasis from pulmonary tuberculosis. 2. Differentiate spasmodic asthma from renal, cardiac and aneurysmal asthma. 3. Diagnose a case of centralized pneumonia in a child of 3. 4. What are the normal findings (microscopic and macroscopic) in feces? (b) What pathologic conditions are diagnosed by microscopic findings in feces? 5. What are the physical signs of incompetency of the pulmonary valve? 6. Give physical signs of aortic obstruction; aortic regurgitation. 7. Differentiate pancreatic cancer from carcinoma of the stomach. 8. Name diseases that may produce hemoglobinuria. Give chemical test for hemoglobinuria.

LEGAL MEDICINE

1. Describe the death-scene in a case in which death is caused from concealed hemorrhage. 2. What are the histologic changes, and in what organs are they most marked, when death is caused from chronic arsenical poisoning? 3. A person claims that his arm is paralyzed as a result following a railroad accident, without external marks. Tell how you would demonstrate before a court the truth or falsity of the claim. 4. As an expert witness, you are required to inform a court whether a will that is in litigation was made by an insane or by a sane person. What facts would you require to enable you to make a decision, and tell what is meant by the term "disposing mind"?

SURGERY

1. In Colles' fracture (a) state usual displacement; (b) name the muscles causing same; (c) give the method of reduction; (d) the permanent dressing you would apply; (e) give the position in which you would place the part in relation to fixed points of the body. 2. In fracture of the neck of the femur: (a) state the usual deformity and the anatomic reason for the same; (b) give an external test-line used in diagnosing lesions in that part; (c) outline two methods of permanent dressings that you would apply in cases of fracture at this point, with the reason for the use of each. 3. Give the normal relations of the bony landmarks of the elbow-joint. State the alterations that occur in (a) anterior luxation; (b) posterior luxation; (c) fracture of the olecranon. 4. Name three forms of intestinal obstruction. Outline the surgical operation that may be required for the relief of each. 5. Give the morbid anatomy of a rectal abscess. Describe the symptoms. Outline the treatment. What sequela may be expected, and why? 6. What is the morbid anatomy, what are the symptoms and what is the surgical treatment of gastric ulcer? 7. Define erysipelas. What are its symptoms and what is a usual treatment? 8. Describe the furniture that is necessary in a well-equipped surgical operating-room.

CHEMISTRY

1. A physician has a patient whose temperature by a Fahrenheit thermometer is 104 degrees, for whom he prescribes as follows: quinin sulphate, 15 grains; sulphuric acid aromatic, 16 minims, and aqua pura, 2 ounces. What is the temperature of the patient by a Centigrade thermometer, and write the prescription by metric terms? 2. If a certain x-ray machine requires 50 milliamperes of current, and the resistance in the machine is equal to 500 ohms, what voltage will be required to run the machine? 3. Define clearly the difference between the terms element and atom; a salt and a compound; an acid and an alkali; organic and inorganic; solution and mixture. 4. What is iodin; what is its atomic weight; what is its specific gravity; what is its symbol, and what is a test for its presence? 5. What is blue vitriol; white vitriol; green vitriol? 6. What is indican? What abnormal condition does its presence indicate? Give the test for indican. 7. How would you test the specific gravity of blood, when only one drop of it is available? 8. What are the solutions, and how would you use them, when testing the urine for suspected sugar?

OBSTETRICS

1. Give signs of fetal death during latter months of pregnancy, and treatment when it occurs. 2. What are the symptoms, and treatment of threatened eclampsia? 3. What are the causes of hemorrhage (a) before labor, (b) during labor, (c) after labor? 4. Give diagnosis, prognosis and treatment of face presentations. 5. When is podalic version indicated? How would you perform the operation? Mention the dangers in its performance. 6. What are the causes of prolonged labor? State the dangers, (a) to the mother, (b) to the child. 7. What are the symptoms of puerperal sepsis? Give your treatment of a case. 8. What are the causes of false labor pains? Diagnose true from false labor pains.

PRACTICE OF MEDICINE

1. Differentiate neuritis from inflammatory rheumatism. Give treatment of neuritis. 2. In what valvular diseases of the heart is dyspnea most marked? Explain the cause of the dyspnea, and treatment you would institute. 3. Give the symptoms, medical and dietetic treatment, and signs of threatening coma in diabetes mellitus. 4. Differentiate chlorosis, pernicious anemia and secondary anemia, and give treatment of chlorosis. 5. What is the significance of dropsy? State how you would recognize by what disease ascites is produced. 6. Called in great haste to a department store during the rush of a Xmas shopping, and find a girl 17 years of age, who was suddenly seized with a severe pain in the right iliac region, upon my arrival I find her with a pulse of 160 per minute, skin and extremities cold, vomiting, with attack of syncope, soon becoming unconscious. Her sister, who is with her, tells me that she has recently complained of pain in the lower abdomen, and more particularly on the right side, and for the last few days with a troublesome diarrhea. Give a probable diagnosis, and tell how you would handle the case. 7. Differentiate acute gastritis, pancreatitis and biliary colic, and give treatment of acute gastritis. 8. Give etiology, symptoms and treatment of acute cystitis.

HISTOLOGY

1. Describe the different elements of which the blood is composed. 2. Describe the structure of an artery. 3. Give the histologic appearance of a cross-section of a long bone. 4. Describe structure of heart-muscle.

EYE, EAR, NOSE AND THROAT

1. Give causes and sequelae of suppurative otitis media. 2. How would you treat a case of acute otitis media before perforation? After perforation? 3. How would you differentiate acute iritis from acute conjunctivitis? 4. Outline the treatment of acute follicular tonsillitis.

DISEASES OF CHILDREN

1. Discuss ophthalmia neonatorum with reference to etiology, pathology, prognosis, treatment and prophylaxis. 2. What would your course be, if called to see a child, aged 6, one of a family of four children, if it presented a suspicious looking membrane in the throat? 3. At what age should a baby be weaned from the breast? Give definite directions for weaning it at that age. 4. Give complete differential diagnosis between measles and scarlet fever. 5. Give symptoms and treatment of bronchopneumonia in a baby of 8 months. 6. Differentiate spasmodic croup from laryngeal diphtheria. 7. Outline treatment of spasmodic croup. 8. What would you advise a nursing mother, with reference to the care of her sore nipples?

PATHOLOGY

1. Describe pathologic characteristics of gastric ulcer. 2. What is the pathology of aneurysm? 3. Describe changes occurring in cartilage in arthritis deformans. 4. What is metastasis? What are the most frequent channels of metastasis?

ANATOMY

1. Describe the heart. Be brief yet comprehensive. 2. What arteries, muscles and nerves would be severed in a cross-section at the middle of the humerus? 3. Describe the thyroid gland. Give nerve-supply, arteries and veins. 4. Name cranial nerves and foramina of exit from the skull. 5. Origin, course and distribution of great sciatic nerve. 6. Name the orbital muscles. 7. Differentiate synarthrosis, amphiarthrosis and diarthrosis. Example of each. 8. Describe the thoracic duct and state the parts of body it drains.

North Dakota January Report

Dr. George M. Williamson, secretary of the North Dakota State Board of Medical Examiners, reports the practical, oral and written examination held at Grand Forks, Jan. 6-9, 1914. The number of subjects examined in was 13; total number of questions asked, 110; percentage required to pass, 75. The total number of candidates examined was 10, of whom 9 passed and 1 failed. Seven candidates were licensed through reciprocity. The following colleges were represented:

Relatives.—Science and literature are not two things, but two sides of one thing.—Huxley.

Book Notices

TUBERCULIN IN DIAGNOSIS AND TREATMENT. A Text-Book of the Specific Diagnosis and Therapy of Tuberculosis, for Practitioners and Students. By Dr. Bandelier, Medical Director of Sanatorium "Schwarzwaldheim" at Schömberg, and Dr. Roepke, Medical Director of the Railway Sanatorium "Stadtwald" at Melsungen. Second English Edition, Translated from the Seventh German Edition by Wilfred B. Christopherson. Cloth. Price, $4.50 net. Pp. 307, with illustrations. New York: William Wood & Co., 1913.

The fact that this book has passed through many editions in the original language speaks for its popularity and for the importance of the subject which it treats. The questions which center around the use of tuberculin are by no means settled, although tuberculin has been before the medical profession for two decades. Whatever may have been presented previously, the views of such men as Bandelier and Roepke cannot fail to be of interest regarding a subject on which they have earned the right to speak with authority. The book deals first with the theoretical considerations affecting the action of tuberculin. The multiplicity of views as to the action of tuberculin and the uncertainty of many of the results of observation and experiment by which such views must be tested render a clear account of these matters extremely difficult. The authors have in general accepted the views of Wassermann and regard the occurrence of hypersusceptibility as a stage or phase in the action of tuberculin which, with the progress of immunity, results in insusceptibility or toxi-immunity. They do not believe, however that it is desirable to prolong the initial stage of hypersusceptibility. The value of hyperemia and of phagocytosis as curative agents is admitted, although the value of opsonins as practical indicators of immunity is regarded as inferior to clinical signs. The authors emphasize "the inferior value of exclusively small doses of tuberculin as expressly demanded by Wright's opsonic theory and by several authors."

The second section deals with the diagnostic use of tuberculin. The method of von Pirquet and the old subcutaneous method receive the approval of the authors, although their limitations are clearly stated. The conclusion which the reader must draw is that none of the tuberculin tests distinguish between latent and active tuberculosis, so that their value is insignificant except in a very limited number of cases. In considering special forms of the disease, however, the value of the tuberculin test in conjunction with the clinical course is accorded a higher position. The local methods of reaction, such as the cutaneous, percutaneous, etc., are to be employed alone in all cases in which the subcutaneous method is contra-indicated. The uncertainty and unreliability of these tests in adults are again distinctly emphasized. The authors' estimate of the subcutaneous test is expressed in the following: "The subcutaneous tuberculin reaction by itself and apart from all clinical methods of examination indicates, as a rule, only that tuberculosis is present, but in conjunction with clinical history, inspection, percussion, and auscultation (focal reaction), it is still to-day the supreme aid to the diagnosis of the active initial stage of pulmonary tuberculosis in adults."

In other forms of tuberculosis in adults the superiority of the subcutaneous test is maintained with few exceptions, especially when focal reactions can be elicited. In surgical conditions the readiness with which the cutaneous test develops gives it a certain advantage. In the tuberculosis of children its great value is acknowledged.

Under treatment the important questions of the method of administration and the dosage are considered. The authors advocate the use of old tuberculin for diagnostic purposes and to secure severe focal reactions, and the bacillen emulsion for general therapeutic purposes. They begin with small doses but advance cautiously, avoiding reactions, but aiming to achieve a toxi-immunity as soon as possible. Other plans of treatment are described and criticized.

The different forms of tuberculin and other specific remedies for tuberculosis are enumerated and an impartial estimate of their value given. In some cases the evidence is regarded as insufficient to permit a judgment to be rendered. In others the opinion is decidedly adverse. Spengler's I K is unqualifiedly condemned as valueless. Marmorek's serum is regarded as still on trial. "In many cases of fresh and purely local tuberculosis it is of value; outside this, its activity seems to be limited, especially owing to the mixed infection so often present in tuberculosis."

The remaining portion of the book is occupied with the specific treatment of tuberculosis in its various forms. The authors are convinced of the value of the treatment; they regard it as applicable to every uncomplicated case of pulmonary tuberculosis, aside from severe incurable forms. In their opinion it can be used in many cases to relieve symptoms when ultimate recovery is not to be expected. Even the pure toxic fever, due to absorption of toxic products from the tubercle bacilli, they say, is by no means unsuited to tuberculin treatment. The contra-indications to the use of tuberculin are thoroughly discussed.

In their conclusions the authors discuss the objections that have been raised to this form of diagnosis and therapy. Especially they oppose the argument that tuberculin has never been proved of value by adequate animal experimentation. They point out that the animals used in such experiments are so susceptible to tuberculosis that a comparison with the phthisis of man is not justified. They believe that tuberculin must become the common property of all practitioners. In order that this may be brought about, a conservative but not too pessimistic work is needed, a need that is well supplied in the volume under consideration.

The American Year-Book. A Record of Events and Progress, 1913. Edited by Francis G. Wickware, B.A., B.Sc., under the Direction of a Supervisory Board Representing National Learned Societies. Cloth. Price, $3.50. Pp. 892. New York: D. Appleton & Co., 1914.

This year-book summarizes the annual progress in history, law, government and administration, economic and social conditions, industries, medical science and the humanities. It contains the statistical matter that is found in all year-books, and in addition there are many excellent articles written by men who are experts in their special fields: The division devoted to medical science includes Anatomy, by C. Carl Huber; Physiology and Pharmacology, by S. J. Meltzer; Pathology and Bacteriology, by Martha Wollstein; Medicine, by Alexander Lambert and Harlow Brooks; Surgery, by Joseph C. Bloodgood, and Public Health and Hygiene, by Selskar M. Gunn. These give a brief review of the progress and the happenings of the various subdivisions during the past year. The book as a whole will be found to contain a vast amount of information in practically every branch of social, professional, manufacturing and commercial life. This information is made readily accessible through the arrangement of the subjects, and especially by an excellent index.

Modern Surgery, General and Operative. By John Chalmers Da Costa, M.D., LL.D., and Samuel S. Gross, Professor of Surgery, Jefferson Medical College, Philadelphia. Seventh Edition. Cloth. Price, $6 net. Pp. 1515, with 1,085 illustrations. Philadelphia: W. B. Saunders Co., 1914.

As this edition is revised, entirely reset and reprinted, it may be regarded, to a large extent, as a new book. The authors suggest, by a poetical quotation, the necessity in such a book of adopting opinions derived from various sources, and in order to present those opinions in their best form, he has frequently quoted exactly from the original sources and has but given his authority for every statement. Much of the value of the book depends on the dogmatic and explicit manner in which most of the instructions are given. The descriptions of surgical procedures even of the minor sort, such as the opening of an abscess, are explicit and detailed. These descriptions omit no opportunity to warn the incautious practitioner of dangers which ought to be avoided. The references to the literature are frequently quite recent. The book is abundantly illustrated, and in every way deserves the confidence of the medical profession.

Medicolegal

Trial by Medical Society of Member Acquitted by Court

(Miller vs. Hennepin County Medical Society et al. (Minn.), 144 N. W. R. 1091)

The Supreme Court of Minnesota holds that the Hennepin County Medical Society, a voluntary association of physicians and surgeons, the by-laws of which provide for the trial of a member for a criminal offense or for misconduct, and provide a penalty by discipline or expulsion, may try a member for acts which were necessarily involved in a criminal charge, which were tried in the district court and of which the member was acquitted. The court says that the plaintiff was acquitted in the district court of the crime of manslaughter in the first degree. The indictment was based on an alleged criminal operation. Charges were preferred by the defendant society against him concerning the matters involved in the criminal charges. The court, on the application of the plaintiff, granted an injunction restraining the society from trying him for the crime of which he had been acquitted, but refused to restrain it from proceeding under its constitution and by-laws to an inquiry and investigation into his conduct relative to the alleged criminal operation. Without determining the precise scope of the injunction, it is clear that it permitted the society to consider acts involved in the criminal charge in disciplining or expelling the plaintiff. His claim was that the facts charged in the indictment could not be made the basis for disciplining or expelling him. But the court knows of no case which holds that a member of a voluntary association, the by-laws of which provide for the discipline or expulsion of a member for crime or misconduct inimical to its being, may interpose as a bar a former acquittal of a criminal charge involving the same acts. Sound reasoning does not support such a claim. The authorities are to the effect that a license to practice medicine may be revoked by the duly constituted authority, and that an attorney may be disbarred by a special judicial proceeding, though the acts relied on for the revocation or disbarment are the same acts on which a criminal charge, resulting in an acquittal, was based. There is less justification for holding that an acquittal is a bar in the trial of a member of an unincorporated association in accordance with its by-laws to which he has assented, when the result of sustaining the charge is no more than a severance of the relations between the association and himself. There is no reason why the plaintiff should not submit to a trial in accordance with the by-laws of the society. The order of the district court is affirmed.

Validity of Quarantine Established by Telephone

(Plymouth Township vs. Klug (N. D.), 145 N. W. R. 130)

The Supreme Court of North Dakota says that some of the defendant's children and a hired man became sick. The physician called pronounced the disease scarlet fever and immediately notified the clerk of the township board thereof. The clerk, on receiving the notice, telephoned to the chairman of the township board, who in turn called up the other members of the board individually on the telephone and discussed the situation. After such discussion, the chairman called up the clerk and directed him to post a quarantine notice on the defendant's farm, which was immediately done. The court considers that the quarantine was regular. While it is true that, under the North Dakota statute, the meetings of the township board must be on three days' notice, yet the court does not believe the statute contemplated the delay of a regular meeting when such an emergency as a contagious disease is presented. To require the board to act in that deliberate manner would defeat the very object of a quarantine law. Besides, the law says that the board shall "immediately" examine, etc. It was the duty of the clerk to establish the quarantine in this case without waiting for the formality of a three days' notice meeting.

AMERICAN GYNECOLOGICAL SOCIETY

Thirty-Ninth Annual Meeting, held at Boston, May 19-21, 1914

(Concluded from page 1988)

Nerve-Blocking

DR. M. L. HARRIS, Chicago: The amount of novocain that can be injected without producing toxic symptoms varies and depends largely on the rapidity of absorption. If a plain watery solution is used and injected in a region where absorption is rapid, from 0.3 to 0.4 gm. may produce toxic symptoms; but if the solution be one which absorbs slowly, from 0.5 to 1 gm. may be used without danger. The more rapid the absorption the less marked the anesthesia. The addition of epinephrin to the solution materially increases the degree and duration of the anesthesia. I have found that by the addition of calcium chlorid in varying strengths, the anesthesia may be prolonged for two or three hours without difficulty, and that a weaker solution may be used than without the calcium chlorid. The formula which has given me the best results is, novocain, from 0.25 to 1 per cent.; calcium chlorid, from 0.25 to 0.5 per cent.; chlorbutanol, 0.8 per cent. in distilled water, to which are added 4 or 5 drops of 1 : 1,000 epinephrin solution to 30 c.c. of the mixture. It is very essential that the mixture be properly prepared, and the method which I use is as follows: The distilled water is sterilized by boiling. The novocain is then added and the boiling continued not to exceed two or three minutes, as prolonged boiling spoils novocain. When this has cooled down to below 150 F., 1 grain of chlorbutanol is added to every 100 c.c. of the novocain solution. Water dissolves only about 0.8 per cent. of chlorbutanol, but 1 per cent. is added merely as an easy way of insuring a saturated solution. The undissolved part simply settles at the bottom. A 2 to 4 per cent. solution of calcium chlorid in distilled water is sterilized, and then the chlorbutanol is added the same as to the novocain solution. The solutions are kept separately and mixed just before using. In this way the percentage of the ingredients may be varied to suit the particular case. The epinephrin should never be added until just before using, as it is very unstable and soon spoils if left standing in the solution, which is indicated by the solution gradually turning a reddish color. The chlorbutanol is added because it has distinct anesthetizing properties of its own, and being soluble in lipoids increases the anesthetizing effect of the novocain. The method is devoid of dangerous and unpleasant complications which so frequently follow the use of general anesthetics. I have done 234 operations on 217 patients under nerve-blocking with six failures and seven deaths.

Spinal Anesthesia in Gynecology

DR. GEORGE GELLHORN, St. Louis: The mortality-rate from spinal anesthesia cannot be determined by statistics. The anesthetic itself seems to have nothing to do with the mortality. The safety of spinal anesthesia depends on its accurate technic. I have done 127 abdominal and 42 vaginal operations without a death. The postoperative care of "spinal cases" is strikingly easy. The usual postoperative symptoms appear in greatly mitigated form, or are altogether absent. Spinal anesthesia enables us to operate with safety on patients in whom ether would be contra-indicated. Minor operations should be reserved for ether narcosis. Spinal anesthesia is contra-indicated in kyphoscoliosis and other marked anomalies of the spinal column, diseases of the central nervous system, profound shock, or marked hypotension from other causes, sepsis, and fevers of unknown origin, and in neuropathic persons. Suppurations and eruptions near the desired site of injection forbid the use of spinal anesthesia until aseptic conditions can be established.

DISCUSSION

DR. FREEMAN ALLEN, Boston: I am not an ardent advocate of spinal anesthesia. A great deal of the condemnation that ether has been receiving lately is due to the fact that surgeons are much too apt to put up with administrations of ether by persons who are comparatively unskilful. If I lived in a community where the services of a skilled anesthetist were not obtainable, I should use spinal anesthesia very largely, if not exclusively.

DR. JOHN O. POLAK, Brooklyn: During the last two years we have used spinal anesthesia in a number of cardiac cases, cases of tuberculosis, diabetes, and in those in which we have had to do obstetric or gynecologic operations. In those extremely severe cardiac cases that complicate pregnancy the use of spinal anesthesia has brought us to a new era of obstetric surgery.

DR. SETH C. GORDON, Portland, Me.: I have given ether and chloroform for over fifty years, and have seen but one death from chloroform and one from ether. The main trouble has been in the administration of these two anesthetics.

DR. M. L. HARRIS, Chicago: Under nerve-blocking there have been no deaths, so it is perfectly safe from that point of view. I have had occasion to operate on a number of patients who had undergone previous operations under general anesthesia, and without a single exception the patients have expressed themselves as infinitely preferring nerve-blocking and would never think of taking a general anesthetic again. Until we find some way of limiting spinal anesthesia to a distinct level or to a certain part of the cord, I think peripheral anesthesia or nerve-blocking must have certain advantages over intraspinal anesthesia.

DR. GEORGE GELLHORN, St. Louis: I have never done anything but gynecologic operations under spinal anesthesia, but I am certain that in operations on the extremities, nerve-blocking will be the method of anesthesia of the future.

Ultimate Results from Surgical Intervention in Cholelithiasis

DR. JOHN G. CLARK, Philadelphia: In all cases in which there is nausea after twenty-four hours, I attach a saline reservoir to the drainage-tube and under 1 foot of hydraulic pressure permit the fluid to drop slowly into the gall-bladder. Great care is observed to avoid the slightest excess of pressure which might induce a rupture about the point of insertion of the tube into the gall-bladder. The drainage has usually been maintained for ten days. Within the last two years I have turned toward cholecystectomy in a greater proportion of cases. If the wall of the gall-bladder is thick and indurated, or if it is dilated and very thin, or if, on inspection of the interior of the organ, the mucosa is eroded or shows a strawberry mottling, I perform cholecystectomy. Occasionally I have closed the gall-bladder without drainage in uncomplicated cholelithiasis, but I prefer to use a simple drain for fear of the rupture of the gall-bladder and escape of bile into the peritoneal cavity. In gynecologic cases with coincident symptoms in the upper abdomen, the gall-bladder is far more frequently the seat of disease than any other organ. Of six fatalities in my series of 160 cases, four of the patients died from destructive results of advanced cholelithiasis. In only two could death be attributed to any defect in operative technic. In one there was a leakage with the formation of a subphrenic abscess; in the other, a peritonitis. These two deaths might have been avoidable. In none of the combined operations in which there were no symptoms attributable to gall-stones was there a fatality.

DISCUSSION

DR. REUBEN PETERSON, Ann Arbor, Mich.: I find that in about one thousand abdominal sections, gall-stones are present in about 12 or 14 per cent. I have adopted the operation of simply removing the gall-stones and draining. I have not removed the gall-bladder in any case. I have found quite a percentage of cases in which I did not think it was advisable to perform any operation on the gall-bladder. I have found an unusually large proportion of cases of cancer with gall-stones. In the pus cases I have refrained from operating on the gall-bladder.

Dr. Philander A. Harris, Paterson, N. J.: I have not removed gall-stones from patients when operating on them for gynecologic troubles in more than half a dozen times. I have removed the gall-bladder in at least 70 per cent. of the cases in which I have operated, something less than 200. Removal of the gall-bladder is good practice.

A Further Development of an Original Technic for Lacerations of the Pelvic Floor

Dr. Barton Cooke Hirst, Philadelphia: For a number of years in my clinic in the University Hospital of Philadelphia, I have had the recently delivered women placed on an operating-table in the dorsal gynecologic position and anesthetized. As a result of this study it is possible to state the following facts in regard to lacerations of the pelvic floor: The pelvic fascia over the levator ani muscle shows a split running parallel with the descending ramus of the pubis: the levator ani is torn loose from its attachment to the pubis and ischium, the injury beginning close to the bone and running downward and inward toward the midline of the posterior vaginal sulcus. The fascia between the levator and the deep transversus perinei shows a triangular split with the apex above. This deep transversus perinei is torn apart in the middle line and the two halves are retracted so that there is a gap of an inch or more between the ends. The junctions of the two halves of the superficial transversus perinei and of the bulbocavernosus muscles are torn apart if the perineal body is injured, as is commonly the case in laceration of the perineum. Expose the component anatomic parts, and unite them separately at the site of the injury to restore their original condition. The levator ani must be exposed by cutting through the pelvic fascia under which it lies. There the belly of this muscle is reattached to the portion arising from the pelvic bones; the deep transversus is brought out of its cavity in which it has retracted and is united in the middle line; the pelvic fascia between the levator and the deep transversus is united, and finally the perineal body is repaired.

Has the American Gynecological Society Done Its Part in the Advancement of Obstetrical Knowledge?

The presidential address by Dr. J. Whitridge Williams, Baltimore, was published in full in The Journal, June 6, 1914, p. 1767.

Iodin as a Sterilizing Agent in Supravaginal Hysterectomy

Dr. I. S. Stone, Washington, D. C.: The application of iodin and alcohol to the vagina and uterine mucosa have been productive of results which appear to approach the ideal. The patient is brought to the operating-table after the proper examination has been made. She is placed in the lithotomy position and a 25 per cent. (1.75 iodin) diluted alcohol tincture of iodin is applied over the genitals and introitus vaginae. The catheter is used immediately after this, and a perineal retractor introduced into the vagina and a volsellum used with which to grasp the cervix. The cervix is dilated to admit the conical nozzle of a 2-ounce glass syringe. An ounce of the same 25 per cent. alcohol solution is then slowly injected into the cavity of the uterus. The fluid is not allowed to remain long nor is great force used. After the injection the cervical canal should again be dilated gently to make sure of the discharge of the excess of the solution. Every part of the vagina is exposed. The operation is preceded by a second application of iodin to the skin over the abdomen, the first having been made before the anesthetic was given. After this the operation is proceeded with as usual and a final application of the iodin alcohol is made to the stump before closing the flaps if there is the slightest intimation that infectious matter has been handled, such as in an appendix, pus-tube, etc. Finally, the iodin solution is applied over the closed abdominal incision before the usual gauze dressings are applied.

Complete Sterilization of the Skin by Iodin

Dr. J. Wesley Bovée, Washington, D. C.: In ten instances, four scrapings were made from skin prepared by the alcoholic solution of iodin (31.2 per cent.) and then subjected to thorough scrubbing with a strong solution of sodium thiosulphate until the iodin color was gone. At the end of five days' incubation, forty specimens from the ten patients showed absolutely no growth.

The Abdominal Cutaneous Reflexes in Acute Conditions Within the Abdomen and Pelvis

Dr. Richard R. Smith, Grand Rapids, Mich.: The behavior of this reflex has been noted in 175 cases in which diseased processes existed within the abdomen. The greater part of them were acute. The reflex is obtained by stroking the skin of the abdomen, which normally produces an almost simultaneous contraction of the rectus and oblique muscles on the corresponding side. The reflex is very constant in healthy young persons, though uncertain in very young infants and in old persons or those with very relaxed or very obese abdominal walls — exceptions which must be definitely borne in mind. In the acute inflammatory diseases within the abdomen it is common to find this reflex involved to a greater or less extent, and the test may be made use of in the diagnosis and in estimating the extent of this lesion. In seventy-five cases of acute appendicitis the reflexes were more or less involved in sixty-five. It is sometimes involved when rigidity is absent. The reflex was commonly impaired over the seat of the lesion when circumscribed, and in more extensive processes the other reflexes were also impaired. It is commonly, though not uniformly, involved in ectopic pregnancy cases. Its normal presence in cases of bowel obstruction would help to eliminate any acute infectious condition, and in the subacute infections of the pelvis I found the lower reflex almost uniformly absent. I believe that, although the test has a certain limited view, it may be of distinct advantage to the surgeon, and it is well worth his careful study.

AMERICAN PEDIATRIC SOCIETY

Twenty-Sixth Annual Meeting, held in Stockbridge, Mass., May 26-28, 1914

(Continued from page 1990)

The Use of Dahlia

Dr. John Ruhräh, Baltimore: Two years ago, in searching for an efficient local application for streptococcus infections of the throat, Dr. Charles Simon suggested dahlia. I started with this as a local application, beginning at first with very weak solutions and soon found that the saturated solution (about a 4 per cent. solution) could be applied to the mucous membrane of the throat or any other part of the body without producing pain or subsequent irritation. The drug seems to penetrate only a short distance and for the deeper affections has no value, but for superficial involvements of the mucous membrane, whether due to the streptococcus or other organisms, the effect was quite striking. In some cases very little effect was noted, but in others there was a marked lessening of the intensity of the inflammation and coincidentally a marked lessening of the constitutional symptoms. It has the advantage over other applications in that it is not painful, does not produce irritation and is markedly antiseptic. Its only disadvantage is its color. For ulcerations about the mouth it may be used by applying a saturated solution or a mouth wash varying in strength from 1 to 1,000 or 1 to 10,000. Dahlia not only kills the offending organism but has a marked effect on the healing. I have used it with remarkable effect on vaccinations that were slow in healing, and on other abraded surfaces, particularly those which were infected. It may be used with reasonable hope of success in skin lesions caused by or accompanied with pus organisms.

Food Intoxications; Sibilant Bronchitis

Dr. B. K. Rachford, Cincinnati: The symptom-groups commonly described in the literature under the titles migraine, recurrent vomiting, recurrent sibilant bronchitis, recurrent coryza, asthma and urticaria, as they occur in children, are, as a rule, closely related food intoxications which can be treated successfully by very much the same dietetic and medicinal treatment. During the attacks sweets, fats, eggs and raw fruits are to be especially avoided. Strawberries, rhubarb, tomatoes, salads, shellfish, tea, coffee, pastry, gravies, cream, cod-liver oil and alcohol are excluded from the diet. If it be necessary to sweeten the cereals and cooked fruits which the child eats, saccharin is to be used instead of sugar. The patient is to have no butter, but skimmed milk is allowed. Eggs in every form, even in cooked foods, are to be eliminated from the diet, and among the raw fruits oranges are to be avoided especially. Beef, mutton, fowl, fish in moderation, cereals, bread and all vegetables not above prescribed, cooked fruits, skimmed milk and thick soups may be taken. About two months after the patient has recovered from the attack, the above diet may be modified by adding one egg a day, then perhaps two weeks later milk containing 4 per cent. fat. Some few weeks later small quantities of sugar may be added for sweetening cereals and cooked fruits. After five or six months the child may return to his original diet, with the exception that he must eat sparingly of sweets and must eat nothing between meals. If the symptom-group returns on the addition of any article of diet, that particular food is to be excluded from the diet.

During the attack the patient is to have all the outdoor air he can get with as little exercise as possible. Constipation should be relieved, milk of magnesia or calcined magnesia being suitable for this purpose. Sulphate of magnesium may be used in small doses in older children. Alkalies in the form of bicarbonate of soda, bicarbonate of potash or citrate of potash should be given in fair-sized doses three or four times a day. In younger children I direct the mother to distribute through the infant's food a teaspoonful of citrate of potash each day. Tincture of belladonna should be given for a short time in two to four minim doses, three times a day. In the intervals the belladonna is discontinued, but an alkali of some form should be given for six or eight weeks. Bicarbonate is best for this purpose.

DISCUSSION

Dr. Fritz B. Talbot, Boston: Dr. Schloss has given an answer as to the cause of this condition in his article on "Egg Anaphylaxis." In a case of anaphylaxis to egg which came under my observation, when immunity to eggs was effected the associated asthma disappeared. I feel sure that this condition is one of anaphylaxis. There may be anaphylaxis to other foods besides eggs. In one patient I started with doses of one sixty-fourth of a grain of egg in capsule, and even this small dose produced a reaction every time it was administered.

Dr. Godfrey R. Pisek, New York: It is not sufficient to stop egg alone, one must stop all foods containing egg. Certain foods such as acid foods bring out an intolerance for certain other foods.

Dr. Henry L. Coit, Newark, N. J.: Many cases with anaphylaxis for eggs have also an anaphylaxis for macaroni. In one case in which I found it necessary to transfer a baby from a milk diet to one in which the carbohydrates would be in the form of cereal, a teaspoonful of wheat jelly was given and caused a rise in temperature, vomiting and prostration. The experiment was repeated with the same result. At the end of two weeks it was tried again and there was a recurrence of the vomiting and prostration. I then vaccinated the child with a minute quantity of wheat jelly. The child now takes cereal jelly and vegetables.

Dr. Walter Lester Carr, New York: Many of these children are susceptible to infection, especially influenza. They belong to the so-called lithemic type, and one frequently finds them with deviated septum, enlarged tonsils, etc. The children having this instability do better if they are starved as in enteritis. They may be given either skimmed milk or lactic acid skimmed milk, and should have general dietetic management.

Dr. I. A. Abt, Chicago: This paper reminds me of "exudative diathesis," a condition in which there is a predisposing constitutional state associated with certain definite symptoms. Under this term Czerny includes exudative inflammatory conditions which may manifest themselves as eczema, scrofula, bronchitis, asthma, urticaria, etc. The symptoms may become more pronounced after eating eggs or milk, or after mild infection. One must not consider this condition a simple anaphylaxis. The class of children who do not tolerate eggs or milk may detoxicate after having taken too much of these foods on starches.

Dr. Charles Gilmore Kerley, New York: These conditions are different from infectious colds. They are nearly always associated with a lithemic, rheumatic or gouty history. In these children the carbohydrates are at fault and the children gain in weight by the elimination of carbohydrate in the form of sugar from the diet. Cream should be eliminated and not more than one pint of skimmed milk daily allowed. Sugar is not at all necessary, children can get the necessary carbohydrates out of ordinary starches and vegetables. In addition to the dietetic management give citrate of soda and keep the bowels open by a suitable laxative.

Dr. Samuel S. Adams, Washington, D. C.: It seems to me the question is one of idiosyncrasy and the problem consists in finding out the article of food for which the idiosyncrasy exists and eliminating it from the diet.

Dr. D. J. Milton Miller, Atlantic City, N. J.: There seems to be some factor other than the food which causes external irritation. I have seen children who could not live at the seashore because of something that caused this internal irritation. As soon as they would go to the mountains they would be all right.

Dr. John Ruhräh, Baltimore: It seems to me we have confused anaphylaxis and acid intoxication.

Dr. Percival Eaton, Pittsburgh: I have had under my observation children who could not take egg and wherever a drop of egg struck the hand or face it caused a red spot.

Infantile Scorbutus and the Pasteurization of Milk

Dr. John Lovett Morse, Boston: In a recent article I called attention to the rapid and progressive increase in the number of cases of scurvy and the coincident increase in the amount of pasteurized milk used. The figures I gave do not prove that the increase is due to pasteurized milk, neither do they prove that the heating of the milk, whether to a temperature of pasteurization or of boiling has anything to do with the etiology of scurvy. They do suggest, however, that there may be some connection and further study along these lines seems to be justified.

DISCUSSION

Dr. Henry J. Gerstenberger, Cleveland, O.: I have had one case of scurvy in a baby fed on casein milk and by simply adding orange juice the child improved rapidly.

Dr. D. J. Milton Miller, Atlantic City, N. J.: I, too, have been finding scurvy on the increase. I have seen twelve cases in private practice during the past two years. In five of these there was a history of bipasteurization of milk.

Dr. A. F. Blackader, Montreal: I have found scurvy on the increase especially during the past winter. I did not alter the food in my cases but simply added orange juice.

Dr. Isaac A. Abt, Chicago: I would like to speak of some animal experiments in this connection. Pigeons when fed on cereals develop polyneuritis, and guinea-pigs fed on cereals are peculiarly susceptible to scurvy. A simple susceptibility has been shown in other animals. Guinea-pigs fed on raw milk develop extra brittle bones. Some fed on milk heated at a temperature of from 60 to 112 C. got scurvy and those fed on oatmeal and raw milk did not show the disease. Milk heated to 90 C. to which oatmeal was added showed antiscorbutic properties. These facts bring up the question as to whether cereal can be considered a factor in the production of scurvy.

Dr. Rowland G. Freeman, New York: Almost all the milk sold in New York City is pasteurized and yet I have not seen a case of scurvy all winter.

Dr. Godfrey R. Pisek, New York: I wonder if it is possible that the laboratory method of pasteurization has anything to do with the production of scurvy.

Dr. Henry Heiman, New York: Scurvy is not due so much to pasteurized milk as to artificial foods. I have seen equally as much scurvy follow other forms of feeding as I have from pasteurized milk.

Dr. J. Crozer Griffith, Philadelphia: Some children get scurvy on raw milk and do well when put on modified milk. We are not in a position to blame pasteurized milk, sterilized milk or any other food. The constant factor seems to be the commercial pasteurized milk, not milk pasteurized at home.

(To be continued)

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal

June 4, CLXX, No. 23, pp. 861-896

1 *Cancer of Uterus. (To be continued.) F. Cobb, Boston.
2 Use of Concentrated Neosalvarsan from Clinical and Serologic Standpoint. J. H. Blaisdell, Boston.
3 *Use of Iodoform Oil in Joints. E. G. Brackett, Boston.

1. **Cancer of Uterus.**—In the fourteen years from 1900 to 1913 inclusive, 367 cases of cancer of the uterus were admitted to the hospital, including cases of cancer of the cervix and cancer of the body of the uterus. Seventy of these were Cobb's personal cases. There were 17 vaginal hysterectomies, 13 for cancer of the cervix and 4 for cancer of the fundus. The immediate mortality was zero. Fourteen operations were done over five years ago, and of these 8 were traced. Two cases were cured, both of them cancer of the cervix, 25 per cent. of cures in the vaginal operation for cancer of the cervix. Since 1910 there were 3 cases, all of which are free from recurrence from one to three years, 2 cancer of the cervix and 1 cancer of the fundus.

There were 27 cases of abdominal hysterectomy for cancer of the fundus. The immediate mortality was 4, or 14.8 per cent. Of the surviving 23 cases Cobb has traced 22, of which 14 were operated on over five years before. Six of these cases are cured, or 42.8 per cent. In addition, one case is free from recurrence 4½ years and one 3¼ years. Abdominal hysterectomy for cancer of the cervix, 89; squamous cell 87 and adenocarcinoma 2. Of 49 simple hysterectomies there was the excessive immediate mortality of 17, or 34.6 per cent. Of the surviving 32 cases Cobb has been able to trace 29. Of these 26 were operated on over five years ago, cured only 5, or 19+ per cent. In addition, 2 cases are free from recurrence from three to four and a half years. Of 40 radical hysterectomies there was an immediate mortality of 9, or 22.5 per cent. Of the surviving 31 cases Cobb has traced all the 31; of these 14 were operated on over five years ago and 7, or 50 per cent., are cured.

3. **Use of Iodoform Oil in Joints.**—Olive oil has been used by Brackett in all of his cases. This method is said to be applicable to cases of old infectious arthritis, with adhesions and with partial obliteration of the capsular cavity, but with no true ankylosis, and without destruction of cartilage; cases of infectious arthritis, in the acute stage, particularly those of Neisserian origin, and more especially the type in which there is one remaining persistent joint, which usually results in ankylosis; cases of primary *synovial tuberculosis* before involvement of cartilage or bone; cases of osteo-arthritis, with marked thickening of capsule and with pannus, in the sensitive stage, but before there has been loss of cartilage. In other words, the method may be used in the affections of the synovial membrane, either when it is desired to keep the surfaces apart, or when it is desired to apply a remedial agent to the joint surfaces.

Several points in the procedure are emphasized: (*a*) The injection is always made by open incision, and not by puncture. (*b*) Sufficient fluid is always left in the joint to keep the capsule under tension, therefore some form of stitch is necessary by which the tension can be maintained at the time of the withdrawal of the syringe. (*c*) The adhesions, in old cases, are broken up before the joint is filled with oil and the capsule closed; other than this no violence is done to the cavity of the joint, and no handling is permitted, particularly of the tuberculous joints. (*d*) Fixation by plaster or splints is seldom used.

The procedure is in no way a substitute for arthroplasty; is not applicable to cases of disease of any origin, in which the Roentgen ray shows involvement of the articular surfaces; but is essentially for those cases, only, in which the abnormal condition is confined to the synovial membrane. In tuberculous cases, the early ones naturally show the most marked definite improvement, and in these cases repeated injections are advocated, preferably at intervals of eight to twelve weeks. This procedure should be considered as an incident in the treatment of the tuberculous synovitis, not a substitute for the fixation and rest. Neither is permanent fixation desirable. The absolute immobilization is, perhaps, quite as disastrous as the other extreme. A daily gentle passive motion, without forcing the arc of motion allowed, is decidedly a benefit, does not increase the activity of the disease, and does prevent the contraction of the capsule and formation of adhesions.

9 Two Neurologic Cases in Pediatric Practice. M. A. Rabinowitz, Brooklyn.

5. **Chlorid of Sodium in Etiology of Neurasthenia.**—In Haig's opinion salt should be increased in every case of debility, marasmus, wasting disease, rheumatoid arthritis and chronic catarrh (intestinal and bronchial) and the effects on nutrition and the excretion of urea watched. He believes that those who do not make a habit of eating salt get a crave for it when the body is running short of chlorid, and that such crave should on no account be neglected. The same occurs to those who do not take enough salt or who sweep out with alkalies or potatoes more than they put in. People who make a habit of reading or working during meals, thus overlooking the taste of their food, are liable to neglect this crave and then serious results may follow. Whenever there are signs of a crave, Haig insists that salt should be taken and continued till chloridism is produced, and the time taken to do this should be noted.

It follows that not only will vegetables, potatoes and alkali sweep chlorid out of the body, but any condition that increases the alkalinity of the blood will do the same. Nearly all wasting diseases, such as chronic dyspepsia, vomiting, diarrhea, chronic pulmonary disease and chronic enteritis of all kinds will do this, hence the marasmus in children which follows so frequently on diarrhea, vomiting or any catarrhal trouble of the intestines or bronchi, may be due in part to sweeping of chlorid out of the body; and Haig has found, as a matter of fact, that very many of these cases have weak hearts due to defective muscular nutrition, and this still further interferes with nutrition and hinders recovery, *producing in children* conditions very closely parallel to neurasthenia in adults.

In his experience such marasmic children do very well and show a most gratifying increase in weight and strength if from ʒss to ʒi or more of chlorid of sodium is added to their food with a small dose of a heart tonic such as strophanthus. It is now his practice to administer chlorid of sodium to all children who are suffering from such troubles, and to use it as a routine treatment in convalescence from summer diarrhea and vomiting.

19 *Predetermination of Sex. I. Bram, Philadelphia.

19. **Predetermination of Sex.**—Bram suggests that sex in offspring is the outcome of a contest between the spermatozoon and the ovum. If the spermatozoon is successful, the outcome is a male; if the ovum, the offspring is a female. This contest varies in one direction or the other by the influence of food. An excess of nourishment in the mother may decide in favor of a female, and a deficiency in the production of a male. Consequently, generous quantities of food with an excess of albuminous nitrogenous substances may decide at conception in favor of a baby girl, and a scanty diet with a very low proteid allowance in favor of a baby boy. Further sex is determined by the activity of the adrenal glands of the prospective mother. According to these theories if a boy is desired, treatment given by Bram is essentially dietary and medicinal, and is persisted in until the fourth or fifth month of pregnancy, when it may be discontinued. Albuminous, nitrogenous substances, such as eggs, meat, fish, cheese, etc., are forbidden; the diet consists essentially of such substances as cereals, fruits, potatoes, milk, buttermilk and butter. Plenty of water is insisted on to keep the kidneys active. In addition the patient is given after each meal a capsule consisting of two grains of the extract of suprarenal gland, combined with four grains of lecithin. Bram cites records of 30 patients in support of his claims.

Medical Chronicle, London

May, XXVII, No. 2, pp. 85-144

1 Leontiasis Ossea. E. D. Telford.
2 *Case of Circumscribed Ulceration of Thoracic Aorta, with Fatal Perforation into Left Lung and Pleura. P. R. Cooper.

2. **Ulceration of Thoracic Aorta.**—The history of Cooper's case is as follows: The patient was a muscular man, aged 45. Up to a few months previously he had always enjoyed good health. About that time he had an attack of "influenza." Since then he had been more or less ailing, complaining chiefly of pain in the left side, which is attributed to "indigestion." He continued at work despite the pain, which at times was very severe. He tried various remedies without benefit. When he consulted Cooper the pain in the left hypochondrium and epigastrium was severe and almost constant, although subject to exacerbation; it was also felt in the back—the upper dorsal region. The pain interfered with sleep, but did not seem to be affected by food. There was a general feeling of languor, and the patient was very easily tired. There was no definite evidence of indigestion. There was no complaint of any cardiac distress. There was no clinical evidence of syphilis or lead poisoning and no addiction to alcohol. Injury was denied, and there was no evidence of the lodgment of any foreign body in the esophagus. The only infectious disease traceable was an alleged attack of influenza shortly before the commencement of the symptoms. The question of diagnosis was difficult. Practically the only symptom was pain, and yet the appearance of suffering and extreme pallor pointed to some organic trouble.

The man was advised to give up work and keep under observation. Powders of codein and phenacetin were given to relieve the pain, and with these he was able to obtain sleep, take more food, and improved so much that of his own accord he went back to work within the week. While on his way to work one morning he collapsed in the street and brought up a large quantity of blood. He died almost immediately. Cooper made a post-mortem the next day. The whole of the left pleural cavity was filled with blood-clot, and at the upper and inner part the pleura and lung were adherent to each other, and to the side of the bodies of the fifth and sixth thoracic vertebra. It was through an aperture in this adherent part that the blood had evidently escaped directly from the aorta into the pleura. The aorta and esophagus were involved in the adhesion and a perforation existed in the aorta about 1 inch in diameter. This hole in the aorta was circular and had a well defined border. The rest of the lining of the aorta was fairly normal except for some superficial patches of atheroma. The sides of the bodies of the fifth and sixth dorsal vertebra were eroded opposite the perforation.

3 *Immediate Results of One Hundred and Sixteen Cases of Excised Carcinoma of Stomach. S. Miyake.
4 Value of Early Diagnosis in Treatment of Ileus. S. Asahara.
5 *Tuberculous Disease of Genito-Urinary Organs as Seen on Post-Mortem Examination. M. Uchimura.

3. **Results of Excised Carcinoma of Stomach.**—Of 116 of Miyake's cases 82 patients were cured and 34 died (29.2 per cent.). Complete excision was done in 2 cases; a wide excision (over 20 cm.) in 18 cases; excision of pancreas in 24 cases (head or part of body); excision of abdominal wall in 3 cases; excision of transverse colon in 5 cases. Of the two complete excisions, one was attended with complete success. The deaths were generally caused by acute peritonitis due to infection from degenerated ulcer of stomach.

5. **Tuberculosis of Genito-Urinary Organs.**—Uchimura examined 1,830 post-mortem descriptions and obtained 629 tuberculous cases. Of these 210 were suffering from either urinary or genital tuberculosis. The frequency of tuberculosis in the urinary organs was found to be in the following order: kidney, bladder, ureter, pelvis of kidney, urethra. Renal tuberculosis was found in 181 cases. Of these 39 were chronic. The pelvis was attacked in 31 cases and chiefly secondary to renal tuberculosis. Among 35 cases of ureteral tuberculosis the kidney escaped only in 1 case; therefore, Uchimura says, the enlargement of the ureter on palpation has diagnostic value in renal tuberculosis. There were 43 cases of bladder tuberculosis and only 4 escaped renal complication. The urethral tuberculosis numbered 6 cases. The frequency of disease in the male genital organs was in the following order—prostate, epididymis, spermatic cord, testicle. The penis was not affected even once. In the female genital organs, fallopian tube, body of uterus, ovary, cervix and vagina were affected in the order named. The external pubic region was never invaded.

6 Pathogenesis and Treatment of Bubo Following Soft Chancre. (Bubon chancreux de l'aine.) W. Dubreuilh.
7 *Orthopedic Treatment of Infantile Paralysis. J. Gourdon.
8 Cancer of Intestine Simulating Appendicitis. L. Verdelet.

7. **Orthopedic Treatment of Infantile Paralysis.**—Gourdon gives an illustrated description of a number of cases of severe crippling from epidemic poliomyelitis in which great improvement followed the use of an orthopedic appliance. The functional improvement realized from exercising, when the orthopedic apparatus got the children up on their feet, was most striking. Surgical and physical measures are usually required also. Even when the crippling is so severe and of such long standing that there is little chance of the child's ever being able to walk freely, yet getting it on its feet by means of orthopedic appliances improves the circulation and spirits, and some control of muscles is regained when they are not already entirely degenerated.

When treatment is begun early and systematically much can be accomplished.

10 *Liver Disease Revealed by Single Symptom. (Les insuffisances hépatiques monosymptomatiques.) P. Le Damany.
11 Freezing Point of the Gastric Contents. (La cryoscopie du contenu gastrique.) L. Meunier.

9. **Comparison of Action of Arsenic and Iron in Anemia.**—Aubertin gives curves from a number of cases of anemia of various types, all apparently showing that arsenic induces the production of new red blood-corpuscles while iron induces production of hemoglobin and favors its being taken up by the corpuscles. In some cases arsenic alone or iron alone may restore the blood to normal, but as a rule both are needed. He advises not to give them together, but successively, commencing with the one which seems to be most needed at the moment.

10. **Monosymptomatic Liver Disease.**—Le Damany reports a number of cases in which persons apparently quite healthy developed some single symptom, such as epistaxis, headache, delirium or convulsions, or a tendency to dropsy developed with practically intact cardiovascular system and kidneys, or the patient ran into a decline which there was nothing to explain except the previously unsuspected liver disease. The importance of recognizing that an otherwise latent liver affection may cause convulsions is evident as treatment for epilepsy is not appropriate in such cases; the liver should be attacked. Purpura is often the first manifestation of liver disease. The true diagnosis may be learned from palpation of the liver and estimation of the urea and urobilin in the urine, by alimentary glycosuria or elimination of methylene blue, excluding all other causes that might cause the symptom under consideration. Sometimes the above single symptoms may alternate or follow each other in turn; more often two or more are associated and then differentiation is easy.

12 *Abscess in the Uterus. (Pyométrie et abcès de l'utérus.) F. Lejars.
13 Tumors in the Central Abdomen. (Variété de tumeurs centro-abdominales.) F. Lejars.

12. **Abscess in the Uterus.**—Lejars classifies these abscesses as intracavitary and intraparietal. In two recent cases of genital prolapse requiring operative treatment the cervix orifice was obliterated, and when he made an opening in it a large quantity of pus escaped, an actual pyometra. Atrophy and retraction of the cervix may lead to this in elderly women, and the distention of the uterus by pus may suggest a tumor, until the pus may be spontaneously evacuated some day. The pus and a tumor may exist together. The pus from a pyometra may make its way into the peritoneum; Krull has reported a death from this cause. When the pus forms, with acute symptoms, after a childbirth or abortion the abscess is generally in the wall of the uterus. Mercadé in 1906 compiled forty-one cases of uterine abscesses, mostly post partum or post abortum but in some cases gonorrhea, traumatism or tuberculosis were the principal factors.

18 Functioning of the Internal Ear. (Ueber die Art der Labyrinthtätigkeit.) O. Goebel. Commenced in No. 20.

16. **Kidney Typhoid and Paratyphoid.**—Klieneberger states that in his two cases the urethra had probably become infected first with the paratyphoid bacilli and they had ascended and settled in the kidneys. The symptoms on the part of the urinary passages were so severe that one of the men was being treated on the assumption of gonorrhea until the paratyphoid bacilli were discovered. The patients came from rural districts and the bacilli cultivated from the urine resembled most closely the bacilli of hog cholera. The symptoms in the first case were those of an acute febrile affection with severe general symptoms suggesting typhoid and symptoms of nephritis, but not much enlargement of the spleen, and signs of slight catarrhal trouble in the lungs. The fever relapsed several times and there were repeated hemorrhages from skin, muscles and gums. In the second case a paratyphoid B infection of the urinary passages set in with fever but the general health was not much impaired at first and the clinical picture did not suggest typhoid. The nephritis persisted for months in both cases but finally seemed to heal completely. The bacilli could be cultivated from the urine for months but never from the blood or intestines. The fever was of an irregular, septic type and the patients did not regain complete health for several months. The bacilli in both were of the hog cholera group with certain adaptations to their hosts. The agglutination titer ran up to 1:327,680 and the blood picture was quite different from that with ordinary typhoid.

28 Relations between Anaphylaxis, Urticaria and Parenteral Digestion of Protein. H. Mühsam and J. Jacobsohn.

19. **Vomiting in Children.**—Tobler remarks that the special excitability of the reflex system in children and the lack of inhibiting influences explain the ease with which vomiting is induced and point the way for treatment. Habitual and periodical vomiting are most frequently encountered in the children of the well-to-do. It is generally found that the child takes little but milk, and is constipated. The diet should be changed to leave out all fluid foods, and all efforts to coax the child to eat should be strictly interdicted. This generally succeeds unless the child is abnormally nervous. In this case, the psychology of the individual child must be studied, and his confidence won. The child must be given the impression that the vomiting is a harmless and trivial matter, not to be taken seriously by anyone in the family. Something special must be ordered to reenforce the therapeutic suggestion, and a glass of mineral water before meals is advisable for this purpose. If the family cannot be relied on, a change of environment may be necessary, best of all to a pediatric clinic.

The habitual morning vomiting of nervous schoolchildren has been best combated in his experience by having the child take breakfast in bed, and eat a little heartier lunch than usual. He advises for the periodical vomiting of neuropathic children to isolate the child at once and ensure absolute quiet and repose, possibly giving chloral or morphin to make the child sleep. The tormenting thirst is relieved by giving an alkaline mineral water ice-cold, a drop at a time, with a pipet. The odor of acetone in the breath at these times suggests that there may have been inadequate intake of carbohydrate in the food, so the diet should be regulated accordingly. If the stomach will not permit eating, the carbohydrate can be given by the rectum—several times a day a nutrient enema of 50 or 150 c.c. of gruel with 5 per cent. grape sugar and a few drops of tincture of opium. If the child can eat, the carbohydrates can be given by the mouth in as compact form as possible, lumps of sugar dipped in black coffee, dry chocolate, crackers, etc., thus tiding the child along until the ordinary food can be resumed. The fact that habitual vomiting is so much more frequent among breast than bottle babies, suggests that the fat in the milk is responsible for it. Tobler emphasizes, however, that the inadequate nourishment and cessation of growth in consequence of the repeated vomiting are less harmful for the infant—even when kept up for weeks—than severe derangement from an unfortunate change to bottle feeding or an unsuitable wet-nurse. Often restricting the amount of the feedings will answer the purpose. If not more than from 10 to 30 gm. are allowed in the twenty-four hours, and this is given fractioned and very slowly, ice-cold, the limit of tolerance can be determined even with stenosis of the pylorus, especially if swallowing of air is prevented.

Nutrient enemas may prove useful for infants; warm breast-milk, cautiously injected, not over 30 to 60 c.c. at a time, has proved the best for the purpose in his experience. Feeding through the duodenal-tube might also be considered. With obstinate spastic vomiting, it may prove necessary to deaden the sensitiveness of the stomach with some local anesthetic given in a weak solution with some acacia by the mouth. Local heat is always useful with spastic conditions in the stomach, and lavage is often of great service, even in acute cholera infantum. It is easy to introduce the moistened catheter (No. 22 or 24); all that is necessary besides is a rubber tube with funnel and glass interpiece.

20. **Syphilitic Myocarditis.** — A supposedly previously healthy young woman with a healthy child of 2 fainted twice, and the second time died, within twenty-four hours, conscious to the last but distressed and with subnormal temperature, pulse 136 to 178 and difficulty in breathing. The heart was dilated and the spleen enlarged. The diagnosis wavered between acute poisoning, terminal nephritis and embolism, but each could finally be excluded and necropsy revealed a syphilitic gumma in the heart. Rosenfeld compares this case with similar ones on record; in 15 of the 49 cases compiled by Stockmann the patients died suddenly and Huchard has found records of 35 with sudden death. In a number of others, as in the case here reported, several hours elapsed after the syncope before death occurred. In 9 of Stockmann's cases the patients died of an intercurrent disease and the gumma in the heart was a necropsy surprise. Differentiation of syphilitic myocarditis is difficult but Rosenfeld accomplished it in another case by heeding the coincidence of the very low blood-pressure and symptoms of mild angina pectoris with dilatation of the left ventricle and aorta, constantly irregular pulse and positive Wassermann. Salvarsan should be given only with extreme caution in such cases as this in itself has a tendency to reduce the blood-pressure and bring on tachycardia. But specific treatment of the syphilis is indispensable, supporting the heart and kidney functioning. Improvement in general health and increase in weight testify that our measures are meeting with success.

21. **Pulmonary Embolism.**—This communication analyzes 18 cases in connection with 22 previously reported by Busch from the same hospital, the aim being to learn if there is a chance for operative measures to succeed in cases of pulmonary embolism. In a fourth of all the above cases death occurred instantaneously; in the others ten minutes or more intervened. The anatomic findings in only 5 of the cases showed that the embolus might possibly have been removed, but 3 of these patients died instantaneously or were too weak for any operation. Two of the 18 in the last series recovered spontaneously. Both were elderly and debilitated and the symptoms were severe at first. Two patients were operated on by Trendelenburg's technic but necropsy showed that the embolism was too extensive for operative relief, both sides being involved. An operation has been done to extract the embolus in 13 cases, but no patient has been saved by it; in Kruger's case in 1909 the patient lived for over five days, succumbing then to secondary infection.

38 The Causal Problem in Medicine. (Kritik des Konditionalismus.) F. Martius.

32. **Friedmann's Remedy for Tuberculosis.**—Windrath is physician in chief to the sanatorium at Beringhaisen, and he states that he applied the Friedmann remedy in twenty-three cases of pulmonary tuberculosis of various stages, with no benefit according to the Friedmann sense "subsidence of toxic symptoms (stitches in the chest, headache, palpitation of the heart, night sweats, fever and cough) and clearing up of the part of the lung involved." In one case an acute aggravation of the disease followed the Friedmann treatment, to which the patient succumbed in a few days. He examined the remedy bacteriologically in some instances and twice found it contaminated with staphylococci. His final conclusion is that he warns against the use of the Friedmann remedy in pulmonary tuberculosis irrespective of the stage of the disease.

33. **Nose Breathing and Pulmonary Tuberculosis.**—Wotzilka has been investigating whether nasal affections are more common among persons with pulmonary tuberculosis than in others. Questions as to whether the individual had always been able to breathe normally through the nose elicited misleading replies, many saying that they had always breathed properly when the passages were found much obstructed. Examination of 67 tuberculous men and 33 tuberculous women disclosed that 45 were unable to breathe normally through the nose, while among 48 non-tuberculous men and 52 non-tuberculous women only 13 of the 100 were unable to breathe normally. This preponderance of 45 per cent. over 13 per cent. among the non-tuberculous is certainly a striking coincidence. The causes of the obstruction were deviation of the septum, hyperplasia in nose or throat, ozena or rhinitis with atrophy. Care to keep the nasal passages and the throat normally permeable may prove important in prophylaxis of pulmonary tuberculosis and may aid in recovery. Especially in the incipient stages every effort must be made to promote the respiration in every way.

34. **Acetonuria Simulated by Malingerer.**—The case is reported of a man who had insured himself in three companies against accident and soon after had his right hand crushed in a machine, and Binswanger found 0.5 per cent. sugar in the urine and acetonuria. As years passed the man seemed to thrive and take on flesh notwithstanding his supposed diabetes and acetonuria. It was finally found that he was in the habit of taking 4 gm. of aspirin every evening when medical examinations were on the tapis. This adds another to the long list of malingerers' tricks.

51 Improved Technic for the Nylander Test for Sugar. (Zur Nylanderschen Zuckerprobe.) Mende.
52 Protein Requirement and Meat in the Diet. (Eiweissbedarf und Fleischnahrung.) K. Kisskalt.

42. **Tuberculosis of the Retina.**—Oloff's two patients were robust sailors and the retinal tuberculous process was primary and isolated in each. He was able to watch the effect on the process of injection of tuberculin, and found it so deleterious that he had to give up the idea of tuberculin treatment. Tuberculous processes of this kind display a marked tendency to retrogress under general dietetic and hygienic measures. Tuberculous processes in the eyes are common at Kiel, where he practices, but not in the form of an affection of the retinal veins as in these cases. They are generally more of a periphlebitis or tumor-like focus.

43. **Sign of Tabes.**—Baeyer calls attention to the abnormal perception in tabetic ataxia of the sensations in the skin when the skin is pressed with the finger and pushed in various directions or a fold is taken up in the fingers and pulled up or down or sideways. A healthy person can always tell in which direction the movements are made, but the tabetic is frequently or constantly mistaken in his perception of the movements. This may occur regularly when surface sensations, like the touch of cotton, are correctly estimated. The derangement probably involves the deep sensitiveness and may prove an aid in diagnosis.

44. **Mesenteric Thombosis.**—Weil emphasizes the great difference in the outlook and indications for treatment as the thrombosis in the mesenteric veins is ascending or descending. With the ascending type, the main trunk of the portal vein is not involved; the trouble is a radicular thrombosis in the portal region. In the other case—the descending type—the portal trunk becomes thrombosed first and symptoms of stasis in the portal system dominate the clinical picture; the spleen enlarges, ascites follows and the veins in the abdominal wall become dilated. The symptoms from the infarct in the intestine may be so stormy that they may mask the portal symptoms unless the latter are sought for with care. Two cases are reported in detail, one of each type. The first was in a woman of 52 with symptoms suggesting collapse from ileus, the spleen not enlarged, the abdomen soft. The operation revealed ascending mesenteric thrombosis and prompt recovery followed resection of the endangered intestine and mesentery. The second patient was a man of 62; the portal vein had become obstructed first and resection of the intestinal infarct naturally had no effect on the portal thrombus. The operation was done on the diagnosis of acute ileus, but the patient died the same day. The spleen was enlarged, the abdomen distended. The first case is the nineteenth on record in which mesenteric thrombosis was cured by an operation. No case of operative recovery is known when the portal vein was the primary seat of the thrombosis. If the spleen is large, there is not much chance of recovery unless the portal vein is opened and the thrombus extracted.

47. **Placentin Reaction in Pregnancy.**—Esch states that he applied juice expressed from placentas to sixteen pregnant and sixteen non-pregnant women according to the usual tuberculin technic and found that all reacted positively. The only difference was that the reaction was much more pronounced in the pregnant women than in the non-pregnant, with the exception of four of the latter whose reaction was on a par with that of the pregnant women.

48. **Typhoid Bacilli Found in Gall-Bladders Removed for Disease.**—Mayer found typhoid bacilli in six of seventy gallbladders that had been removed for various reasons. Paratyphoid bacilli were found in another, thus bringing to 7 per cent. the cases with positive findings, indicating a chronic bacilli carrier. In his district, Landau, there are already ninety-five chronic carriers under constant supervision, and the above six will have to be added to the list as the records show that removal of the gall-bladder does not always put an end once for all to elimination of typhoid bacilli, although it may help for a time.

49. **Death after Operation for Exophthalmic Goiter.**—Huismans' patient was a woman of 33 with exophthalmic goiter which had gradually developed from a puberty goiter. She had borne three children and the urine was free from sugar and albumin, but she had suffered for some time from a sense of oppression in the chest. The right lobe of the thyroid and part of the left was removed, and she died the eighteenth hour. The thymus and spleen were very large and strips of acute inflammation were found in the kidneys—all testifying, he says, to pluriglandular intoxication. He suggests that thyroid treatment should be given after thyroidectomy; since he has made a practice of this he has had no more mishaps of the kind (since 1910).

55 Traumatic Rupture of the Bladder; Recovery. P. L. Della Torre.
56 Hernia of the Appendix Vermiformis. G. Lionti. Commenced in No. 19.

54. **Lime Salts for Filling Cavities in Bones.**—Marcozzi expatiates on the advantages of the method of filling up a cavity in bone with material which will not act as a culture medium or as a foreign body, and which is gradually absorbed. The Mosetig filling for the purpose is a mixture of 60 parts iodoform, 40 parts spermaceti and 40 parts oil of sesame, but Marcozzi thinks the iodoform can be dispensed with—cases of poisoning are known from its use—while the spermaceti and oil are of no direct help in bone repair. He remarks that Senn came nearer to the ideal in his suggestion to use decalcified bone, but—strange to say—he discarded the very substance, the lime, which is most needed for bone repair. Marcozzi reports considerable experimental research and one clinical experience which have demonstrated, he asserts, the feasibility and great superiority of using lime salts to fill the bone cavity, thus supplying the bone directly with the elements it needs to produce new bone. He uses a mixture of equal parts of calcium carbonate and phosphate, sterilized by dry heat or by adding water and boiling until all is evaporated. The cavity is first lightly touched with tincture of iodin, and then the friable lime mixture is smoothed out with a Wolkmann spoon and shoveled into the cavity where it serves at once to arrest all bleeding. It is not absorbed so promptly as some substances, which is a further advantage, while the fact that it is all finally absorbed is a great improvement over any substance which is left in the cavity as a foreign body.

JOURNALS INDEXED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1914

The following journals have been indexed in the Current Literature Department of THE JOURNAL during the past six months. Any of the foreign journals, except those starred, will be lent by THE JOURNAL to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days. Only one journal may be borrowed at a time. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Domestic journals can be obtained by sending the approximate amount direct to the respective publishers. Thus most of the journals indexed are accessible to the general practitioner, no matter where he may be located.

EXPLANATION OF THE USE OF THE INDEX

This is an index not only to the reading matter in THE JOURNAL, but also to original articles in the principal medical periodicals of this and other countries. The reading matter appearing in THE JOURNAL is distinguished by the use of **black-faced numerals.**

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "T," Therapeutics; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an "Original Article" in THE JOURNAL.

This is a subject index and one should, therefore, look for the chief word, with the following exceptions: "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "D" and "S." Matter pertaining to the Association is indexed under "American Medical Association."

All matter is indexed under the most important word of the heading used in THE JOURNAL, and also under the subject heading. For instance, abscess of the brain will be found under "abscess," as well as under "brain." Such titles as "ocular manifestations, etc." have been indexed under "Eye." Cross references have been liberally used.

The figures in parentheses refer to the paragraph, the number following to the page in THE JOURNAL.

ABDERHALDEN and Fauser's reaction in dementia praecox, ***1701***

This reference is to an original article in THE JOURNAL, as shown both by the star and by the black-faced numerals indicating the page.

ACID, acetyl-salicylic, effect of addiction to, ***797***

This reference, as indicated by the black-faced figures, is also in THE JOURNAL, and on turning to page 797 we find an answer to a question in the Department of Queries and Minor Notes.

ABSCESS, cerebellar, *symptom of,* (91) ***1764***

In this reference, the (91) indicates that the article is in the Current Literature Department and the fact that the page number is in black-faced type shows that the article is abstracted and discussed in THE JOURNAL. Turning to page 1764, we find (91) refers to an article by M. Mann in the *Münchener medizinische Wochenschrift,* April 21.

ADENOMAS, multiple, and etiology of prostate enlargement, (121) 573

The fact that in this last reference the page is given in ordinary type indicates that only the title of the article is given. Turning to page 573 we find that the numeral (121) refers to a paper on that subject by J. A. Gardner and B. T. Simpson which appeared in *Surgery, Gynecology and Obstetrics,* January.

In the AUTHOR'S INDEX are the names of the authors of articles which have appeared in THE JOURNAL of the American Medical Association and of articles that have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals. The black-faced numerals indicate that the article is in THE JOURNAL, either in full or in abstract. The star (*) preceding the page number, indicates an original article.

EXPLANATION OF THE USE OF THE INDEX

This is an index not only to the reading matter in The Journal, but also to original articles in the principal medical periodicals of this and other countries. The reading matter appearing in The Journal is distinguished by the use of **black-faced numerals.**

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "T," Therapeutics; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an "Original Article" in The Journal.

This is a subject index and one should, therefore, look for the chief word, with the following exceptions: "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "D" and "S." Matter pertaining to the Association is indexed under "American Medical Association."

All matter is indexed under the most important word of the heading used in The Journal, and also under the subject heading. For instance, abscess of the brain will be found under "abscess," as well as under "brain." Such titles as "ocular manifestations, etc." have been indexed under "Eye." Cross references have been liberally used.

The figures in parentheses refer to the paragraph, the number following to the page in The Journal.

> ABDERHALDEN and Fauser's reaction in dementia praecox, *1701

This reference is to an original article in The Journal, as shown both by the star and by the black-faced numerals indicating the page.

> ACID, acetyl-salicylic, effect of addiction to, 797

This reference, as indicated by the black-faced figures, is also in The Journal, and on turning to page 797 we find an answer to a question in the Department of Queries and Minor Notes.

> ABSCESS, cerebellar, symptom of, (91) 1764

In this reference, the (91) indicates that the article is in the Current Literature Department and the fact that the page number is in black-faced type shows that the article is abstracted and discussed in The Journal. Turning to page 1764, we find (91) refers to an article by M. Mann in the *Münchener medizinische Wochenschrift,* April 21.

> ADENOMAS, multiple, and etiology of prostate enlargement, (121) 573

The fact that in this last reference the page is given in ordinary type indicates that only the title of the article is given. Turning to page 573 we find that the numeral (121) refers to a paper on that subject by J. A. Gardner and B. T. Simpson which appeared in *Surgery, Gynecology and Obstetrics,* January.

In the Author's Index are the names of the authors of articles which have appeared in The Journal of the American Medical Association and of articles that have been listed from week to week in the Department of Current Medical Literature as having appeared in other journals. The black-faced numerals indicate that the article is in The Journal, either in full or in abstract. The star (*) preceding the page number, indicates an original article.

SUBJECT INDEX

A

ABBOTT'S treatment for scoliosis, (76) 77, (51) 577, (136) 582, (98) 1286, (42) 1365
ABBREVIATIONS in medical references adopted by German medical press, style-book for, (79) 578
ABDERHALDEN and Fauser's reaction in dementia praecox, *1701
  investigations of, on amino-acids in blood, 621—E
  metabolism and new views of, (41) 330
  ninhydrin in urine in pregnancy, dialyzable product reacting to, *436
  protecting ferments, specific nature of, (133) 498
  protective enzymes of body, (46) 1433
  serodiagnosis by dialysis, (90) 580, (120) 656, (106) 891
  serodiagnosis by dialysis, adsorption phenomena as source of error in, (107) 890
  serodiagnosis by dialysis, demonstration of protective ferments against bacteria, by means of, (112) 818
  serodiagnosis by dialysis, relation between thyroid, parathyroids and thymus, shown by, (137) 819
  serodiagnosis, experimental study of, 1499—ab
  serodiagnosis in dementia praecox, and Halvar Lundvall's remedy, (66) 572
  serodiagnosis in psychiatry, (99) 168, (99) 1199, 1576
  serodiagnosis of cancer, (120) 163, *599
  serodiagnosis of cancer and tuberculosis, (60) 1126
  serodiagnosis of pregnancy, (44) 75, (47) 166, (120) 163, (100) 168, (42) 330, (127) 582, (185) 1210, (18) 1436
  serodiagnosis of pregnancy, neither specific nor reliable, reply to article asserting, (120) 1205
  serodiagnosis of pregnancy not specific and not reliable, (92) 1057, (150-152) 1207
  serodiagnosis of syphilis, 1920—ab
  serodiagnosis, present status of, (33) 1993
ABDERHALDEN serodiagnosis suggests epilepsy is of nature of anaphylaxis, (82) 1291
  serodiagnosis, technic, (109) 420, (138) 740, (129) 1059, (199) 1210, (108) 1307, (174) 1517
  serodiagnosis, theoretical explanation of, (56) 1126, (124) 1369
  sero-enzyme diagnosis of syphilis, *1002
ABDOMEN, acute, diagnosis, (40) 1201
  acute, diagnosis and surgical technic of, 404—ab
  adhesions, postoperative, postural treatment, (109) 238
  anatomic changes in organs in thorax and, after intraperitoneal injection of camphorated oil, (70) 243
  artificial ureter made from wall of, (120) 573
  automassage of, (114) 1130
  closure of, in face of sepsis, (11) 1048
  colic in upper, in children, recurring, (107) 420
  condition of upper region of, and disease of gall-bladder, (47) 71
  cutaneous, reflexes in acute conditions in pelvis and, 2048—ab
  cysts, two cases, (23) 334
  diagnostic sign in injuries of, new, (126) 574
  differentiation of diseases by symptoms on part of vegetative nervous system, (104) 817
  diseases, correlation of appendicitis and, 1500—ab
  diseases of upper, (65) 1506
  echinococcosis of (192) 1209
  emergencies, (16) 1436
  emergencies, triple syndrome in, (2) 412
  fat, abnormally, reduction of, (128) 1131
  gauze, left in, (29) 1053
  gunshot wounds of, (107) 333, (53) 572, (111) 1361, 1748—ab
  gunshot wounds of, rational treatment on battlefield, (86) 1286
  head and trunk position in treatment of surgical lesions of, (116) 1199
  incision, technic of closing, (83) 1049
  infections, dangers and treatment of, (44) 1289
  injuries, time element in operative treatment, (60) 730
ABDOMEN, iodin, use of, in, (109) 885
  pain with scarlet fever, violent, (192) 250
  pressure, intra-abdominal, and distribution of blood with enteroptosis, (74) 1128
  pressure on, influence of smoking and, on gastric hunger contractions, (3) 1840
  Ptosis of: See Splanchnoptosis
  roentgenoscopy in diseases of (67) 1506
  sarcoma, diffuse, (158) 820
  strengthening, valuable treatment, (103) 490
  Surgery: See also Laparotomies
  surgery and gynecology, contributions to, during 1913, (22) 571
  tissues of, adventitious, (5) 159
  troubles, associated, (45) 1120
  tumors in central, (13) 2052
  tumors, inflammatory processes forming, (78) 1291
  tumors, localization of, by palpation, (59) 1055
  tuning-fork in diagnosing outlines of solid and hollow viscera of thorax and, and of certain pathologic conditions, (22) 650
  wall, separation of, from fascia, (62) 416
  wounds of, (78) 1512
ABEL'S, J. J., "vivi-diffusion," (83) 1360
ABLATIO placentae, references to, 1983
ABORTION at third month, eclampsia after, (125) 582
  criminal, gangrene of cervix of uterus from injection of caustic for, (24) 733
  criminal, in absence of pregnancy, attempts at, (172) 173
  epizootic, in mares, etiology of, (92) 162
  febrile, bacteriologic research in, (155) 81, (57) 578
  febrile, treatment of, (119) 1697
  habitual, and internal secretions, (73) 244
  increasing number of, (57) 1290
  induction of, and sterilization at one sitting, (104) 581, (45) 971
  induction of, in pernicious anemia and uncontrollable vomiting, (99) 1512
ABORTION, jaundice after, (61) 578
  manslaughter in death from attempted, 563—Ml
  physician's willingness to commit, not punishable, 1836—Ml
  streptococcus, active and conservative treatment, (110) 581
  treatment of, (108) 497
ABSCESS: See also Cellulitis; Felon; Phlegmon
ABSCESS *and partial exfoliation* of both cartilages and perichondritis of arytenoid cartilages due to typhoid, (24) 69
  appendicitis with localized, removal of appendix in, 405—ab, *1004
  appendix infection with, should appendix be removed at primary operation? (20) 235
  appendix, secondary hemorrhage from deep epigastric artery after operations for, (47) 493
  bacillus colon, in prostate, (149) 1132
  brain, *449, 1582—ab
  brain, diagnosis and treatment, (92) 1360
  brain, due to bacillus coli communis, (98) 648
  brain, due to fusiform bacilli, *446
  brain, otitic, (81) 572
  brain, otitic, and *mastoid* exenteration, exhibition of, by nature, (19) 68
  brain, otitic, showing necessity of early mastoid operation, (165) 1362
  cerebellar, and otitic meningitis, (10) 1200
  cerebellar, diagnostic value of pointing test in, (91) 1360
  cerebellar, symptom of, (91) 1764
  ethmoid, due to bacillus fusiformis of Plaut-Vincent, (74) 490
  extradural, toxic exhaustive insanity associated with chronic suppurative otitis media, labyrinthitis and, (22) 241
  fish-bone causing, with hematemesis controlled by hot water, *375
  fixation, turpentine, in children, (56) 243
  Inflammation of lateral columns of pharynx leading to, (22) 1195
  intestines, repeated ileus from unusual, (88) 418

- ABSCESS, intrathoracic, in children, roentgenoscopy of, (128) 421
  - liver, (139) 575, (99) 1361
  - liver and lung, amebic, long-standing, (19) 644
  - liver, emetine in, (14) 1364
  - liver, emetine in amebic dysentery and hepatitis, (11, 19) 1363
  - liver, emetine in amebic dysentery or, (71) 76
  - liver, following gall-bladder disease, (113) 490
  - liver, metastatic, operative treatment, (69) 417
  - liver, multiple, diagnosis and curability of, (140) 1853
  - liver, operative treatment of, (13) 1363
  - liver, treatment of, (12, 17) 1363
  - lung, in diphtheria and paralysis of circumflex nerve, (11) 1585
  - lung, in infant, operative treatment of, (107) 1764
  - lung, operative treatment, (3) 1047
  - multiple, meningitis following measles and pneumonia, ending in recovery with, (59) 966
  - nose septum secondary to furuncle of vestibule, (17) 1123
  - nose septum, treatment of, (31) 1283
  - orbit, and optic neuritis complicating dacryocystitis, (112) 163
  - orbit, from infection through ethmoid, two cases, (120) 73
  - otogenous, in temporal lobe, (86) 737, (100) 817
  - peritonsillar, treatment of, (128) 1692

septic, and mouth sepsis, (27) 886
spleen in, (76) 1128
splenic, (33) 414
splenic, and streptothrix, (93) 580
splenic, chronic, and Banti's disease, (20) 1586
splenic, in children, (53) 336
splenic, in infant, cholesterin in, (160) 248
splenic, infective nature of certain cases of splenomegaly and, (30) 576
splenic, with splenectomy, (32) 1689
toxic, (125) 1443
vitiated air, importance of, in etiology of, (159) 1132
ANESTHESIA, (58) 1286
anesthetics and the anesthetist, (58) 810
anoci-association, (59) 409, (111) 411, (82) 966, 1428—ab
blocking inferior maxillary nerve, (116) 1936
blocking of intra-orbital and mental nerves in their cutaneous distribution to induce operative, (85) 1049
brachial plexus, Kulenkampff's method of, *1629
chloroform, in light of physiologic research, (12) 575
combined general and local, needlessness of, (18) 1431
deaths following, 1098—E
early, 925—ab
epinephrin in adrenals after, variations in, (50) 735
ether, by open method, (82) 1928
ether, death during, due to status lymphaticus, *1014
ether, failure of respiration during, (54) 236
fatalities during, resuscitation in, 1499—ab
fatalities, secondary, (65) 2000
gas-oxygen, (105) 490
gas-oxygen novocain, (54) 1994
general, prognosis in, (158) 1132, (96) 1512
general, with isopral by the rectum, dangers of, (75) 888
general, with pantopon and scopolamin, (126) 80
hedonal, intravenous, experimental research on, (55) 415
in labor, (86) 72
injuries and fatalities from, means of lessening, (117) 811
instantaneous, hypnotism and poison needle stories in the light of science, 799—E
insufflation, modified technic for, (88) 889
intratracheal, (12) 1047
intratracheal, apparatus for, simple, *37, (15) 333, (14) 1357
intratracheal, combined manometer and safety valve for, (14) 333
intratracheal, from standpoint of nose, throat and oral surgeon, new instrument for catheterizing trachea, (101) 163
intratracheal insufflation, Auer-Meltzer, intubation for, technic of, (168) 249
intratracheal insufflation, introducing tube in, *1547
intratracheal insufflation of ether, (17) 333
intratracheal insufflation, present status of, (112) 1697
intratracheal insufflation, surgery of aorta under, experimental, (72) 653
light, dangers of, (17) 1436
local, (46) 1843
local, after-pain with operations under, (129) 1698
local and sacral, for laparotomies, (92) 2000
local and venous, (66) 1049
local, dosage of cocain and other drugs for, *196
local for bubo operations, (36) 1759
local, for eye and face operations, (125) 649, (157) 1206
local, for phimosis operations, (66) 1512
local, for submucous resection of nasal septum, *1724
ANESTHESIA, local, gastroenterostomy under, (105) 1122
local, in hernia, (125) 1123
local, in surgical practice, (145) 1060
local, pain after, (123) 892, (168) 1208
local, prostatectomy under, (108) 648
local, pyramidon keeps off pain in wound after, (181) 173
local, rectum operations under, (132) 1755
local, with alypin in tuberculous adrenal, sudden death after, (151) 172
local, with colpo-perineorrhaphy, technic for, (52) 651
modern, (134) 1200
modern methods of, (123) 246
nerve trunk, and carbolization in nose surgery, (100) 163
nitrous oxid, (55) 1994
nitrous oxid, in animal experimentation, (63) 1359
nitrous oxid-oxygen, (146) 80
nitrous oxid-oxygen, apparatus, portable, *1326
nitrous oxid-oxygen in prolonged, (110) 1361
nitrous oxid-oxygen-ether apparatus, construction of, previously unemphasized feature in, *35
novocain, in nerve-blocking, 2047—ab
oil and ether, (37) 241, *364, (84) 572, (22) 881, (112) 1199, 1429—ab, (82) 1691, 2048
parasacral, (79) 816
practical, (54) 1359
sacral, epidural injections, (125) 1514
scopolamin, combined with local, in ophthalmic surgery, (58) 1695
scopolamin-morphin, in obstetrics, 1829
scopolamin-morphin, in obstetrics, McClure on, 1815—E, 1912—C
spinal, (55) 577, (56) 887
spinal, action on kidneys of, (130) 1294
spinal, in gynecology, (5) 1753, 2047—ab
spinal, infectious meningitis following, (165) 81
spinal, stovain, action on liver and kidneys of, (69) 494
ANESTHETICS, (89) 237, (118) 811
action of, in suppressing cell-division, (55) 1120
administration of, legal status of trained nurses in, (38) 1993
anesthesia and the anesthetist, (58) 810
danger of combining, (158) 341
diagnosis and, (25) 1364
herniotomy without, sensations during, (152) 248
in labor, (86) 72
influence of kidney lesions in determining selection of, and surgery risks, (49) 331
liability of employer for death of employee when layman administers, 562—Ml
negligent administration of, 864
novocain and local, (53) 1359
selection of, on basis of its ultimate physiology, (110) 237
society for Scotland, 862
tension of ether vapors in man, determination of, (83) 1123
volatile, common, mode of action of, (83) 1122
ANESTHETISTS, American Association of, meeting, 1736
educational qualification for, (43) 882
non-medical, (128) 1199
ANESTHETOMETER, Connell, and Waller gas balance, calibration of, (82) 1121
ANEURYSM, (87) 811
and injured blood-vessels, operative treatment, indications for, (129) 421
and injury to nerves on battle-field, (43) 1997
aortic, 1686—ab
aortic, relapsing fever in, 1837—ab
aortic, simulation of, by other aortic and heart diseases, (11) 1436
arteriovenous, (3) 649
arteriovenous, of external iliac vessels with wound of external iliac vein, (8) 1357
blood-vessels transplantation (95) 168

ANEURYSM, congenital, in young rabbit, (21) 1123
  embolic, as complication of acute endocarditis, (81) 1934
  erosion of tissues by, (35) 1048 ..
  extrathoracic, of transverse arch of aorta, (31) 1437
  growth and perforation of, (72) 1128
  hemothorax caused by rupture of dissecting, *1242
  hepatic artery, (158) 173
  Matas operation for, (98) 1691
  operations on, technic for, (54) 1587
  popliteal, (32) 1201
  popliteal, disappearance under antisyphilitic treatment, (100) 1691
  ruptured, of descending aorta, (18) 333
  sinus of Valsalva, *1878
  thoracic aorta, wiring with electrolysis for, *1217
  thoracic aorta, with paralysis of left diaphragm and hour-glass contraction of stomach, (116) 1287
  thoracic, of unusual size, case of, (30) 1437
  traumatic, in Balkan wars, (97) 1589
ANGER, sudden bilateral blindness, following fit of, with permanent bilateral central scotoma resulting, (15) 1841
ANGINA and scarlet fever due to alimentary anaphylaxis, (133) 80
  Ludwig's: See Ludwig's Angina
  pectoris, (101) 2001
  Vincent's: See Vincent's Angina
ANGIOMA face, ligation of vessels and injection of formaldehyd in, (54) 1055
  in tissue around tendon, (59) 416
  lids and brow, (12) 1283
  primary, in muscle, (47) 1289
ANGIOSCLEROTIC changes in bones, (114) 1514
ANGIOSPASM, cerebral, phenomena due to, (4) 1929
ANILIN dyes, effect on growth of bacteria, (52) 331, (19) 728, (7) 1430, (62) 1926
  poisoning, probable case of, 314-C
ANIMAL and plant tissues, finer structure of, (29) 645
  Experimentation: See also Vivisection
  experimentation, nitrous oxid anesthesia, in, (63) 1359
  experimentation, progress in therapeutics based on, (115) 1765
  experimentation, resolutions on, by Federation of American Societies for Experimental Biology, 138
  food, influence of, on aorta and internal organs of rabbits, (200) 1210
  growth of, after nursing period on mixed and on carbohydrate diet, (76) 1291
  magnetism from medical standpoint, (142) 892
  spirits and nervous impulses, 542—E
  tattoo marks for identification of, in laboratories, (37) 1120
  that think, (124) 818
ANKLE, arthrodesis of, by Cramer's method, and relations with genu valgum, clinical and experimental study, (65) 416
  dislocation, upward, (58) 815
  fractures at wrist and, mathematical calculation of prognosis in, (128) 732
  tuberculosis, treatment and results, 222 cases, (96) 78
ANKYLOSIS, hip-joints, complete, cesarean section for, (79) 1763
  intra-articular bony and fibrous, of temporomandibular articulation, arthroplasty for, *1783
  joints, attempts to mobilize, end-results, (94) 238
  joints, mobilization of, (93) 237
  joints, multiple, congenital, (57) 166
  joints, operative restoration of function (104) 1368
  joint, treatment of, (17) 1288
  knee, deformity from, operative treatment, (73) 167
  mandible, *1014
  maxilla, extra-articular, due to foreign bodies in scalp for ten years, (24) 885
  spine, extreme, (86) 2000
ANKYLOSTOMIASIS: See Uncinariasis
ANOCI-ASSOCIATION, (111) 411, (82) 966, 1428-ab
  and cancer of cheek, (9) 1758
  in prevention of surgical shock and postoperative pain, *1777
  technic and results of, (59) 409
ANOMALIES, constitutional, diagnosis of, between 20 and 50, (96) 1367
ANOREXIA nervosa in infant, (117) 490
ANTENATAL hygiene, influence on infant mortality, (2) 968
  pathology, need for research in, (35) 1694
ANTHRACOSIS, lung, histologic evidence of disease, importance of, (88) 162
  lung tuberculosis and allied disorders, prevention of, (1) 649
ANTHRAX bacilli, passage of, through tissue of tonsil, (10) 1119
  bacilli, peptone culture medium for, (96) 974
  diagnosis of, from cerebrospinal fluid, (193) 250
  immunization against, (64) 1291
  insect transmission of, experimental, 320—ab
  serum, 537
ANTHROPOLOGIC research on island near Sumatra, (133) 1936
  study of portraits of Shakespeare and Burns, (1) 1123
ANTHROPOLOGY, physical, measurements of 3,425 Coreans, (158) 1854
ANTIBODY and animal species, (32) 335
  content, acetic-acid reaction in serum parallels, (100) 419
  formation in typhoid, (29) 571
  heterogenetic, (104) 338
  production of, in animals treated with bacillus of rhinoscleroma, (168) 1517
ANTI-CIGARETTE league treatment for cigarette-smoking, 224
ANTIFERMENTS, proteolytic action of ferments and, colored plates to show, (83) 1851
ANTIGENS, chemicals for, in biologic tests, (132) 1205
  cholesterinized, in Wassermann reaction, *363, *1458, *1620, 1829—C
  for meiostagmin test for cancer, (181) 1209, (121) 1765
  partial, (71) 1291
  potent elements in, for Wasserman reaction, (117) 1442
  reaction in tuberculosis, (44) 814, (49) 1126
  syphilis, practical studies on, and cholesterinized extracts, (30) 69
  Wassermann, standard, method developed for obtaining, (23) 1842
ANTIGONOCOCCIC serum in gonorrhea, *1462
ANTIMENINGITIS serum, sources of danger in, 1661—E
ANTIMONY and soamin, trypanosomiasis treated with, (7) 1287
  in spirochete and trypanosome diseases, (115) 339
  trioxid in trypanosomiasis, experimental, (7) 1693
ANTIPERISTALSIS, roentgenography of colonic peristalsis and, (83) 966
ANTIPLAGUE serum, 1495
ANTIPYRETICS, (69) 1127
ANTIPYRIN, action of acetanilid, phenacetin and, 1982
ANTIRENNIN, action of, on digestibility of milk, 1488, (75) 1695
ANTISEPTICS and germicides in inflammations of mucous membranes, *2030
  versus germicides, (113) 411
ANTISERUM, new cancer, results of work with, (74) 1507
  viperine, new method of obtaining, (13) 412
ANTISNUFF act constitutional, 1424—MI
ANTISPITTING campaign, physicians caught in, 622—E
ANTISTREPTOCOCCUS serum, 537
ANTITETANUS serum, serum sickness after injection of, eleven years after injection of diphtheria antitoxin, (50) 1438
ANTITOXIN, absorption of agglutinin and, injected subcutaneously, (44) 1285
  alkali releases toxin from combination with, (70) 1290
  and thyroid, relation between, (29) 335
ANTITOXIN, content of blood of normal horses and its production in natural conditions of life of these animals, (186) 342
  content of normal serum, (80) 495
  diphtheria, anaphylaxis occurring in horse asthma after administration of, (32) 1925
  diphtheria, asthma and hay-fever as contra-indications of, 1038
  diphtheria, danger and prophylaxis of anaphylaxis from, (68) 1291, (67) 1999
  diphtheria, history of, (84) 1367
  diphtheria, in bacilli-carriers, (67) 1291
  diphtheria, in blood of normal person, presence of, 1810—E
  diphtheria, prophylactic use, (110) 1764
  diphtheria, serum sickness after injection of antitetanus serum, eleven years after injection of, (50) 1438
  dosage of, and serum sensitization, (45) 1284
  doses of, massive, (85) 883
  eruption confused with erythema, due to, *1013
  Ontario board of health supplying, 1182
  reminiscences of introduction of, (48) 1365
  tetanus, 128, 931, 1890, *2025
ANTITRYPSIN, serum, nature of, (60) 1927
ANTITUBERCULOSIS association, field of work of, (13) 1583
ANTIVIVISECTION case, Pennsylvania, 1331-E, 1341, 1423-ab
  fiasco, 1025—E
  literature, charge of human vivisection as presented in, *659
ANTIVIVISECTIONISTS, 320-ab
  medical support of, 541-E
ANTRUM, maxillary, ventilation rather than drainage for sinus disease with special reference to, (66) 71
  sinus suppuration, technic of intranasal operation for, (14) 1123
ANURIA, kidney functioning with, from reflex action (72) 816
  surgical treatment of, (139) 1435
  total, from mercuric chlorid poisoning, (115) 976
ANUS, artificial, intestinal, prolapse through, (90) 1129
  artificial, permanent, technic for, (135) 421
  artificial, technic for obliteration of, (123) 582
  atresia, congenital, (86) 817
  congenital opening of, into urethra, case of, (110) 1442
  diagnosis of common diseases of rectum and, (76) 883
  fistula, cause and treatment, (121) 818
  fistula hemorrhoids and operative treatment of, (118) 1755
  imperforate, (58) 1585
  imperforate conditions of rectum and, treatment, (38) 166
  imperforation of rectum and, with autopsy findings, (140) 1435
ANUSOL suppositories, 395—P
ANXIETY neurosis, observations on, (60) 1049
AORTA, abdominal, embolus in, (133) 421
  and internal organs of rabbits, influence of animal food on, (200) 1210
  aneurysm, 1686—ab
  aneurysm, relapsing fever in, 1837—ab
  descending, ruptured aneurysm of, (18) 333
  dilatation of, in Heller-Doehle's aortitis, (75) 1366
  extrathoracic aneurysm of transverse arch of, (31) 1437
  foreign-body injury of esophagus with perforation of, (65) 578
  percussion of, from back, (134) 892
  sclerosis of, sign of, (92) 975
  stenosis of, and atresia of pulmonary artery, congenital, fatal, (172) 173
  surgery of, under intratracheal insufflation general anesthesia, experimental, (72) 653
  syphilitic disease of, inherited, (97) 1764
  thoracic, aneurysm of, wiring with electrolysis for, *1217
  thoracic, aneurysm of, with paralysis of left diaphragm and hour-glass contraction of stomach, (116) 1287
AORTA, thoracic circumscribed ulceration of, with fatal perforation into left lung and pleura, (2) 2051
AORTITIS, Heller-Doehle's dilatation of aorta in, (75) 1366
  syphilitic, (103) 73, (40) 1365
  syphilitic, diagnosis and treatment of, (27) 1283
APHASIA and anarthria, (140) 1755
  and apraxia, (139) 1758
  and mind disease, (89) 580
  anemia with hemianopsia and, severe, (97) 244
  clinical interpretation of, (49) 1584
  in Japanese, (82) 1441
  mental diseases and, from medicolegal point of view, (127) 1755
  motor, or anarthria, (63) 1197
  motor, reeducation of speech in, (47) 1054
  sensorimotor, (128) 1755
  theories of, (48) 1584
  transcortical motor, with paralysis and inability to read correctly, (148) 1516
  traumatic sensory, (23) 1694
  visual, subcortical, case of, 406—ab
APHTHOUS fever, (182) 500
APOPLEXY: See Brain, Hemorrhage
APPARATUS: See also Instrument
APPARATUS, artificial pneumothorax, *40, (138) 582, *929, (9) 1119
  blood for cultures, tube for collecting, *774
  blood transfusion, new, *775
  brace for treatment of scoliosis, *1325
  diphtheria culture-tube, improved, *39
  electric, for local passive exercise of muscles, simplified, (121) 245
  endoscopic galvano-cautery for operations on bladder orifice, *1088
  ether and chloroform bottles, *38
  face protector, (78) 490, *1326
  for determining carbon dioxid tension of blood, (191) 82
  for determining minute quantities of carbon dioxid, special, (44) 409
  for determining urea content by urease, *1558
  for differential atmospheric pressure, improved, (82) 417
  for estimation of chlorids in urine, *1399
  for excentric extension of stumps after fracture of leg, (72) 167
  for protection against infection in nose and throat examinations, simple, *454
  for transfusion by aspiration injection method, (82) 1049
  for use in operations on open thorax, (41) 1358
  for using constant stream of water in water-cooled tube, (10) 329
  inflatable disk for lung compression, (122) 818
  intratracheal insufflation, *37, (13, 15) 333, (14) 1357
  manometer and safety valve combined for intratracheal anesthesia, (14) 333
  mirror attached to blood-counting pipet, *455
  motor-meal and lavage tube, new, *453
  mouth breathing, to prevent (30) 75
  neosalvarsan in concentrated solution, intravenous injection of, *454
  nitrous-oxid-oxygen-ether, construction of, previously unemphasized feature in, *35
  nitrous oxid-oxygen, portable, *1326
  nose splint, external metal, simple, efficient, (29) 1584
  screw-holder for bone-surgery, inexpensive, *455
  spring splint as aid in tabes dorsalis, (142) 171
  stomach tube, Smithies, *453
  urethra irrigation, improved cut-off, *455
APPENDECTOMY, cicatricial pericolitis following, (52) 1761
  hernia and neuralgia after, (176) 1700
  in general practice, (6) 164
  suppression of urine in boy after, cured by double nephrotomy, (18) 1693
APPENDICITIS, (89) 1129, 1751—ab, (83) 1928

APPENDICITIS, acute, during chicken-pox, (31) 1509
  acute, 560 operative cases, (94) 338
  acute, pre-peritonitic stage of, (8) 733
  acute, present position of, and complications, (12) 885
  acute, suppurative, complicated by gangrene of ileum, (31) 1125
  bile tract infections in relation to duodenum ulcer and, (34) 409
  cancer of intestine simulating, (8) 2051
  chronic, dyspepsia due to, (46) 1048
  chronic, remote effects of, (56) 883
  correlation of, and other abdominal affections, 1500—ab
  diagnosis of, (75) 966, (14) 1930
  diphtheria, with, (101) 419
  diverticulitis, and (183) 500
  enameled ware, cause of chipping of, 864
  etiology of, (125) 1293
  false, of pregnancy, (35) 1847
  fifty years ago and today, (99) 338
  following ingestion of shot for "Cuban itch," *1322
  genitalia, female, and (130) 892
  hematuria with, (36) 1125
  in children, (5) 968, (30) 1053
  in children, diagnosis of, (38) 970
  in infants and children, acute, (27) 235
  in Switzerland, (107) 338
  in the elderly, (139) 493
  increased resistance of peritoneum to infection in treatment of, (78) 1934
  inheritability of, (54) 415
  insurance policies against, 1030
  leukocyte count in doubtful cases of, importance of, (6) 733
  leukocyte curve, with, (198) 1518
  limping as symptom of, (39) 734
  liver with, (47) 1997
  medical aspect of, (118) 967
  megacolon and, two cases, (167) 1444
  operable and non-operable, (48) 572
  operative and post-operative treatment, (81) 1507
  operative mortality in, (82) 1507
  operative treatment, (93) 333
  oxyuris, and (193) 342
  peritoneal congestion due to, 1267
  peritonitis due to, treatment of, (81) 1512, (98) 1696
  pregnancy and high mortality of, (113) 818
  removal of appendix in cases of, with localized abscess, 405—ab, *1004
  roentgenoscopy of chronic, (136) 247
  suppurative, (133) 164
  threadworms and, (22) 1759
  with mechanical, intestine obstruction, (166) 1444
  with symptoms resembling those of kidney colic, (10) 733
  without symptoms, (134) 164, (58) 1359
APPENDIX abscess, secondary hemorrhage from deep epigastric artery after operations for, (47) 493
  blood-vessel disturbances in diseased, (93) 168
  cancer (44) 1438, (30) 1689
  cancer, in girl of 20, (19) 241
  cancer, primary, (89) 410
  cyst of, 328-ab
  cyst, pseudomyxomatous, of, *1795
  foreign bodies in, (87) 572
  genital disease and, (30) 2053
  hernia of, (56) 2054
  hernia, retroperitoneal, into ileo-appendicular fossa, (83) 1845
  infection with abscess formation, should appendix be removed at primary operation? (20) 235
  intestinal strangulation, acute, due to abnormally misplaced, (5) 487
  intussusception of, vermiform (32) 1693
  operations on kidneys, bladder and, (117) 245

  bacilli, iodin fumes applied to throat to exterminate, (149) 172
  bacilli may penetrate all organs, (83) 1367
  bacilli, transformation of, (55) 1365
  bile culture medium in bacteriologic diagnosis of, (102) 244
  bronchitis due to, fetid, acute, (95) 586
  changes in hypophysis in experimental, (132) 656
  circulatory failure in, mechanism of, (3) 407
  cold weather and spreading of, 1408—E
  culture-tube, improved, *39
  diagnosis and treatment, (21) 69
DIPHTHERIA, epidemiology of, in Cleveland for 1913, (55) 71
  eye coloration in relation to incidence, severity and fatality of scarlet fever and, (56) 76
  family predisposition or immunity to, (115) 78
  gangrene of foot in, (53) 1510, (30) 1996
  in Cuba, 1487
  in heart blood and in organs, distribution of, (75) 336
  intubation in, (17) 881
  lactic acid bacilli, effect of, on, *510, 1037—C, *1779, (89) 1928
  lung abscess and paralysis of circumflex nerve in, (11) 1585
  milk-borne epidemic of, (19) 1925
  myocarditis in, gallop rhythm and extra systoles in, (105) 1058
  nasal, in infants, (85) 1367
  paralysis following, (62) 1286
  Ponder's staining method for specimens, 476
  prophylaxis of, (109) 1368, (153) 1591
  pseudo-diphtheria and, infection in mastoid wound, (94) 1360
  quarantine in, (92) 1122
  school and, (121) 1205, (148) 1369
  simulating glandular fever, (161) 499
  susceptibility to, test for, 1176—E
  syphilitic sore throat, diagnosed as, subsequent eruption confused with antitoxic erythema, *1013
  toxin skin reaction, (137) 171
  vaccination against, (160) 1207, (77) 1366
  vaccination, Behring's method, 51, (79) 417, (76) 578, 1738, (50) 1998
  vagina, (8) 807
  vagina, simulating gonorrhea, (80) 1292
  without membrane, (80) 1292
DIPLEGIA, cerebrocerebellar, 1045—ab, (51) 1584
DIPLOCOCCUS lanceolatus in pemphigus vesicles, (170) 1699
DISEASE and crime, literature on relation of, 1350, 1494
  and garrison ration, (81) 1286
  chronic, overlooked causes of, 1637—T, 1724—T, 1808—T
  Mexican invasion and dangers of, 1403—E
  natural defenses of the body against, (70) 883
  of ancient time, as illustrated by Coptic mummies, 1022—E
  revocation of licenses of physicians obtaining fees on representing that incurable diseases can be cured, validity of statute providing for, 402—Ml
  "sure cures" for every, 826—ab
  transmission by insects, (41) 572
  transmission by insects, literature on, 316
  transmission of, American insects and arachnids concerned in, (27) 330
  transmitted by milk and milk products, 1684—ab
  unusual, prevailing in epidemic form at Buhi, Ambos Camarines, Philippines, (97) 333
DISINFECTANT action of certain bacterial stains, (42) 1284
  Krelos, Mulford, 537
DISINFECTION: See also Sterilization
DISINFECTION after contagious diseases, 2032—E
  by calcium oxid of feces in typhoid, simple and effective method, (39) 330
  internal, in rat cancer, (129) 1205
DISPENSARY abuse, (44, 45) 1994
  dental, for Albany schools, 783—E
  fee proposed for use of, 1269
  for alcoholics and lung patients, combined, 1184
  of Johns Hopkins Hospital, organization of, (104) 648
  tuberculin, league, (109) 339
  tuberculin treatment, (97) 817
  tuberculin treatment of children, (81) 337
  work, physicians should receive pay for, (118) 1361
DISSECTOR, tonsil, sharp, with double pillar retractor, modified Jansen-Middleton nasal septum punch, (80) 490
DISTEMPER and epidemic poliomyelitis of dogs, *678
  in horses, isolation by government veterinarians of causative agent of, in Philippines, 704—E
  paratyphoid bacilli causal agent of, in dogs, (120) 79
DISTRICT OF COLUMBIA January report, 1833
  medical news, 706, 1262, 1973
DIURESIS, action of digitalis on blood-pressure and, (43) 1760
  influence of, on elimination of salvarsan, (74) 1933
  with chronic nephritis, influence of calcium chlorid on, (116) 738
DIURETIN and theobromin sodium salicylate, 1108—P
DIVERTICULITIS, *1624
  and appendicitis, (183) 500
  and sigmoiditis, (154) 1060
  chronic, obstructive pelvic lesions associated with, (14) 963
  of colon, (43) 1048
DIVERTICULUM, acquired, in lower intestine, diagnosis of, (105) 1852
  congenital, in intestines and consequences, (138) 1936
  in omentum, congenital, relics in adults of, (56) 735
  Meckel's ileus from, (141) 1131
  multiple, of intestine, (54) 1998
  of urinary bladder, removing, improved method, (55) 489
DIVORCE and alcoholism, 51
DOREMUS-HINDS ureometer, improved technic for, *514
DOROTHY REED type of primary pseudoleukemia of spleen, (84) 162
DORSAL position during puerperium as cause of retroversion of uterus, *607
DOSE, amendments in stating doses of medicine in British pharmacopeia, suggested, (26) 650
  fatal, minimal, analysis of problem of, and relationship to time factor, (21) 1509
  for children, calculation of, (165) 658, (139) 1853
DOUCHES, lactic-acid vaginal, advantages of, during pregnancy, (140) 1131
  medicated, effect of, on bacteriology of vagina, (78) 1763
  nasal and nasopharyngeal, safe and effective method of douching, *1398
  vaginal, (138) 421
  vaginal, ante partum, in prophylaxis of puerperal infection, (41) 336
  vaginal, mercuric chlorid poisoning due to, *535
DOWNS, JEAN, Get Slim, 715—P
DOYEN, law-suit between assistant and, 391
DRAINAGE for ascites, (157) 172
  lumbar, by meningocele sac as drinage tube in hydrocephalus internus, (70) 1755
  of ascitic fluid into subcutaneous cellular tissue, permanent, (48) 166
  of bladder following suprapubic operations, (71) 1286
  of upper intestine loop for relief of ileus, (96) 238
  tube in laparotomies, (55) 1695.
  ventilation rather than, essential in sinus disease, special reference to maxillary antrum, (66) 71
  vaginal, *2027
  versus immediate suture of common duct, *1373
DREAMS, (117) 1361
  causation of, (46) 882
  fairy tales as determinant of neurotic symptoms and, (98) 1199
  interpretation of, and theory of psycho-analysis, (80) 1755
  inventorial record forms of use in analysis of, (69) 1434
  meaning of, (74) 572, (131) 1361
DRESSINGS, cotton, (112) 1205
  leg, means of facilitating application of, *1090
  material, protection of granulations by, *1247
  sterilization of, by Rochester steam sterilizer, 1112
  [illegible] and method [illegible] 967
  [illegible] versal, (38) [illegible]
  universal, of new-born infant, (60) 1290
DRUG, action of, selective, on nervous system as aid to diagnosis, (121) 491
  administering of, abuse of subcutaneous method of, (117) 976
  anaphylaxis from, (177) 1209
  and fever, 302—E
  dispensing physicians and quality of drugs sold, 56—C
  do we give, too often, (110) 1367

DRUG, ecbolic, pharmacologic action of, (1) 486
eruptions, (112) 1361
habit a menace in South, (97) 648
habit, a public health problem, (22) 808
habit forming, Harrison bills and Nelson amendment on, 1276—ME
habit in Tenessee, 1427—ab
habit, institutional treatment, (127) 411
habit, Towne-Lambert elimination treatment of, (200) 1758
influence of, on secretion of milk, 1681
passage of, through placenta, (118) 892
physiologic test of, 53
potency of, summation and enhancing of, by combining them, (115) 1590
prescribing, desirability of knowledge in using and of simplicity in, (35) 1284
specific, action of, nature of, (106) 169
tests of vegetative nervous system, (87) 1441
variation in, (57) 1584
DRUGGIST: See Pharmacist
DRUNKENNESS: See also Alcoholism; Inebriety
DRUNKENNESS, Massachusetts legislative commission on, work of, 1913, (39) 160, 1985—ab
prevention of, 1665—ab
DUCKLINGS, modification of diet prevents epidemic disease in, (35) 1996
DUCT Botalli, elastic tissue in post-fetal, occlusion and obliteration of, in sus scrofa, (55) 646
Botalli, patent, *34, (21) 813
thoracic, tampon buried in, to plug fistula in, (135) 1131
thoracic, varices in, (99) 1764
thyrolingual, persisting, as cause of cough, (106) 1130
DUCTLESS GLANDS, and growth, (107) 1755
hyperfunctioning, roentgenotherapy of, (50) 1054
hypertrophy of thyroid, experimental, and effect of excision of, on other, (5) 407
in acute thyroid enlargement of pregnancy, description of, (22) 413
influence of, on hair and teeth, (205) 1210, 1334—E, (86) 1441
psychic disturbances associated with disorders of, (10) 1503
relation between, (40) 1289
relation to disease, (46) 572
surgery and, (80) 1050
DUDLEY-REYNOLDS operation for sterility, (4) 159
DUKET cure blows up, 1347—P
DUMB, education of deaf and, difficulties of aural instruction, (76) 1844
DUNTLEY universal electric drill, *1087
DUODENOSCOPE, inflating gastroscope and, (102) 731
DUODENUM, cancer, primary, with involvement of common bile-duct, (21) 1053
chemistry of, (35) 1587
contents, enzyme activity of, examination for diagnostic purposes of, (28) 69
contents, typhoid bacilli in, obtained through tube, (142) 657
displacement, retroperitoneal, traumatic, with absolute obstruction, gastrojejunostomy and duodenumjejunostomy, (52) 161
division of, at duodenojejunal junction treated by closure of divided ends and gastrojejunostomy, (31) 1693
fistula, treatment of, (17) 1585
foreign bodies in, (98) 1589
incision in, with calculus in common bile-duct, (72) 77
injuries to descending portion of, during removal of right kidney, accidental, *343
kinking at first and second portions of, (98) 811
management of stump of, (122) 582
mobilization of, (145) 1362
operations on stomach and, (145) 1766
retroperitoneal rupture of, (8) 885
roentgen-cinematography of stomach and, (26) 1688
roentgenology, history and technic of, (104) 1513
DUODENUM, roentgenoscopy of stomach and, practical application of, *1071
rupture of, caused by blow, (4) 1585
stenosis of, chronic, in children from pressure by root of mesentery, (176) 82
stricture of, due to abnormal folds of anterior mesogastrium, *1211
stump, management of, after resection of stomach, (77) 1588
surgical diseases of, (73) 237
toxemia, following rupture of *759
tube, (125) 1853
tube, autodrainage of stomach and duodenum for diagnostic purposes, (85) 337
tube, examination with, simplification of, *911
tube, feeding by, technic for, (118) 420
tube, visualization of intestinal tract, upper, by roentgenology in conjunction with, (80) 1434
tumor of stomach and, benign and malignant, serial roentgenoscopic differential diagnosis of, (151) 1516
ulcer, (132) 170, (196) 250, (140) 657, (144) 1206, (33) 1584, (153) 1766
ulcer, and vegetative nervous system, (70) 417
ulcer, bile tract infections in relation to appendicitis and, (34) 409
ulcer, care after operation for, (138) 1205
ulcer, diagnosis, (77) 417
ulcer, etiology of, (156) 172
ulcer, gastro-duodenostomy for, (118) 739
ulcer of stomach and, (69, 70) 1198, 1500—ab
ulcer of stomach and, cholelithiasis from, differential diagnosis, *263
ulcer of stomach and, diagnosis and indications for operation in, (69) 966
ulcer of stomach and, diagnosis and treatment of, (56, 68) 966, (32) 1284
ulcer of stomach and, early diagnosis and medical treatment of, 805—ab
ulcer of stomach and, etiology and surgical treatment of, (79) 1198, 1501—ab
ulcer of stomach and, experimental production of, (96) 1696
ulcer of stomach and, medical standpoint of, (17) 2051
ulcer of stomach and, nut milk in, (92) 1696
ulcer of stomach and, perforated, peritonitis from, operative treatment, (52) 415
ulcer of stomach and, perforated, treatment of,. (44) 494, (82) 1512
ulcer of stomach and, perforating, acute, (27) 75, (32) 1048, (32) 1290,. (9) 1357
ulcers of stomach and, perforating, in vicinity of pylorus, (73) 647
ulcer, perforated, right shoulder pain in, (17) 74, (122) 1435
ulcer, perforation of, spontaneous recovery after, (40) 493
ulcer, peritonitis from, (147) 819
ulcer, recurrences following operation, (14) 570
ulcer, roentgenology of, 1419—C, (14) 1758
ulcer, roentgenology of, with reference to gastric hyperperistalsis, *980
ulcer, value of polycythemia for diagnosis of, (110) 1755
DUODENUMJEJUNOSTOMY and
[illegible]atic
of
ob-
[illegible]ntal
by
obliteration of sinus, (99) 163
fascia flap to close defect in, (76) 1512
hemangio-endothelioma in frontal region of, removal of, (9) 1431
DUST and disease, (29) 241
in air, and in fresh air schoolrooms, new method of determining, (75) 883
industrial, as factor in bronchopulmonary disease, (70) 1203
DWARF growth from achondroplasia, (138) 892
DYES, anilin, action of, on bacterial development, (52) 331, (19) 728, (7) 1430, (62) 1926
DYES, azo, in tuberculosis in guinea-pigs, (17) 1992
hair and fur, dermatoses from, (110) 245
of benzidin group, 1477—E
DYNAMITE caps, effects of explosion of, on tympanum and external ear, (69) 332
DYSENTERY, amebic, (91) 811
amebic and bacillus carriers, 1267, (44) 1510
amebic, chaparro amargosa in, *1530
amebic, emetine and ipecacuanha in, (18) 1364
amebic, emetine hydrochlorid cures, of thirteen years' duration, *534
amebic, emetine hydrochlorid in, (71) 77, 475—C, *501, (20) 1364, 1583—ab
amebic, emetine in, (34) 236, (73) 572, (2) 963, (15, 23) 1363
amebic, emetine in, from lamblia intestinalis and spirochetes, (109) 890
amebic, emetine in hepatitis and, including liver abscess, (11) 1363
amebic, emetine in liver conditions and, in Kathiawar, (21) 1363
amebic, in Darjeeling district, treatment, (16) 1363
amebic, quinin in *1009
amebic, relation of water-supplies to, 783—E
amebic, salvarsan-copper in, (86) 580
among children, (44) 336
bacilli, variability of, (159) 1756
bacillus, bactericidal action of organic silver salts and other antiseptics on, (8) 412
epidemic, bacillus aerogenes capsulatus in, (90) 162
epidemic in children, (155) 1207
epidemic in Fiji islands, (7) 812
in Raipur central jail, (17) 165
in young children, (134) 819
spirilla and amebas in intestines with, (45) 735
toxin, chemistry and toxicology of, (130) 1443
treatment of, (156) 1206
DYSMENORRHEA, 1750—ab, (24) 1753
and amenorrhea, (129) 1123
atropin in, (157) 341
congestive, physiologic treatment of, *1297
constitutional, (138) 1756
cure of, (130) 819
intranasal treatment of, *6
thyroid or ovarian extract treatment of, (62) 243
DYSPEPSIA, appendicitis, chronic, causing, (46) 1048
as seen by surgeon with illustrative case histories, (136) 1435
chronic, 1724—T
diet in development of dental caries and, in children, (13) 1200
fluids in, (41) 414
in infants, sweetened milk for, 401—ab
in tabes dorsalis, (72) 888
DYSPHAGIA in larynx tuberculosis, relief of, (160) 658
DYSPITUITARISM, three cases, (11) 165
DYSPNEA, heart and kidney, 619—E
paroxysmal, in heart and kidney patients, (9) 74
treatment of, (79) 889
DYSTOCIA from distention of bladder of fetus, (65) 652
DYSTONIA musculorum deformans, case of, (65) 1197
DYSTROPHY, diet and diarrhea in infants, (4) 649

EAR, absence of, congenital, (94) 163
  anatomy of, in Japanese, (126) 1765
  and throat complication of leukemia and pseudoleukemia, (112) 648
  and throat department of Royal Infirmary of Edinburgh, reports for 1913 from, (16) 1123, (12) 1930
  catarrh of eustachian tubes and, diagnosis and treatment of, (30) 1048
  catarrhal conditions of, and nose troubles, (59) 730
  cauliflower, treatment of, (71) 237
  conservation of functions of nose, throat and, (108) 1199
  cysts in, external, (116) 1514
  deformity of, and webbed toes and fingers, (118) 1293
  diseases, diagnosis in, errors of, (22) 492
  diseases, *middle*, simulating disease of external canal, (88) 1286
  diseases of eye and, differential diagnosis, (43) 572
  diseases of nose, throat and, violet ray and *ozone* in, (71) 811
  diseases, prevention and treatment, (99) 580
  diseases, rational treatment, 1500—ab
  diseases, traumatic, and workmen's compensation, (67) 1762
  disturbances and trauma of head, (87) 731
  drums, relaxed, (101) 1199
  effects of explosion of dynamite caps on tympanum and external, (69) 332
  epithelioma, squamous, of mastoid and, (22) 1048
  examination of eyes and, of schoolchildren, (36) 1196
  eye, nose and throat work, accessory facts to, of interest to physicians, (132) 649
  functioning of internal, examination and testing, (79) 77
  in exophthalmic goiter, (64) 1927
  instrument for demonstration of compensatory movement of eyes for which ear is responsible, (76) 973
  internal, anatomy of, (97) 1129
  internal, disease plus cerebellum disease, (58) 887
  internal, functioning, mechanism *of*, (49) 1932, (18) 2052
  joint disease merely expression of chronic infectious process in nose, throat or, (87) 245
  middle, chronic suppuration of, (41) 1843
  middle, disease, suppuration in parotid gland in children originating in, (116) 1853
  middle, suppuration of, acute and chronic, (48) 71, (121) 163
  middle, suppuration of, danger-signals in, (15) 1995
  nascent iodin in throat and, (71) 1203
  pathologic conditions in nose, throat or, reflex to disease of teeth, jaws *or parotid gland*, (21) 1048
  re-educating, by exercising the hearing, with small siren, (33) 813
  sepsis, general, originating in, operative treatment of, (59) 1999
  speculum, improved, *40
  suppuration, chronic, conservative treatment of, (95) 1122
  suppuration, chronic, in infant, (204) 174
  suppuration, chronic, operative disposal of, (20) 1048
  syphilis with diagnosis by, (143) 340
  systemic diseases and diseases of nose, throat, eye and, (99) 1122
  tuberculosis of, (97) 1122
EAR-ACHE, inhalation of volatile oil of mustard, relieves toothache and, (105) 1130
  obscure origin, (13) 968
ECHINOCOCCOSIS, (131) 1294
  abdomen, (192) 1209
  brain, (96) 1057
  in muscle or kidney, (118) 1936
  internal, operative treatment of, (138) 1294
  liver, treatment, (15) 492
  rectovesical, (10) 963
  with rupture of diaphragm, operation and recovery, (109, 110) 411
ECHIS carinata, preparation of antivenomous serum for phoorsa or, and toxicity and hemolysing power of venom, (12) 412
  venom given in nature by, at a single bite, (17) 969
ECK'S fistula, production of meat intoxication in dogs with, (83) 1441
ECLAMPSIA, (133) 732, (131) 976
  after abortion at third month, (125) 582
  after removal of ruptured uterus at term, (142) 819
  antepartum, emptying uterus in treatment, (73) 333
  at Königsberg, (117) 1059
  cause and cure, (77) 811
  cesarean section, abdominal, in treatment of, (16) 1431
  cesarean section for pre-eclampsia at twenty-fourth week, (21) 650
  diabetic, (133) 1369
  hysteria simulating, in primipara at thirty-seventh week of pregnancy, (113) 1287
  labor in, rapid, (9) 575
  lipoid chemistry of blood in pregnancy, amenorrhea and, (168) 81
  misleading statistics in regard to, (143) 819
  nitrogen of blood, total non-protein, in pregnancy and, (10) 1431
  pituitary extract and salt infusion in, (230) 84
  pleural, (100) 1204
  prophylaxis and treatment of pre-eclamptic toxemia and, (8) 1758
  puerperal, cause and treatment, (84) 648
  treatment of, (18) 1283
  with absence of albumin, but generalized hard adema, (45) 882
ECTOPIA lentis, (151) 1435
ECZEMA and internal diseases, (201) 250
  basic principles in, (53) 1754
  bromid eruption simulating blastomycosis, or *912
  chronic, roentgenotherapy of acute inguinal lymph-adenitis and, (38) 1759
  coal tar in treatment of, (62) 1202
  formaldehyd, rubbing with emery paper and wearing gloves cures rebellious, (113) 420
  hands, roentgenotherapy in, (67) 237
  marginatum of toes, *1076
  treatment of, (28) 1586
EDELMANN'S acoustics for otologists, (95) 163
EDEMA, acidity and nephritis, 2033—E
  action of theobromin and sodium salicylate on, (84) 495
  and hemorrhages from poisons, (125) 1443
  and osmosis in infants and children, literature on, (31) 1120
  angioneurotic, (8) 2050
  Fisher's alkaline-saline therapy in nephritis and, 1687—ab
  generalized, hard, with absence of albumin in eclampsia, (45) 882
  in infants, (40) 730
  legs, persistent, hereditary, with acute exacerbations, (63) 1754
  macular area of retina, case of, (64) 161, (125) 1846
  nephritic, pathogenesis *of*, (121) 1131
  operative treatment of varices of legs and, technic for, (170) 342
  pathology of dropsy and, chiefly in relation to colloids, (15) 240
  with anemia, (112) 1368
EDIPUS complex, report of five cases, (11) 1688
EDITOR and physician, (70) 332

HEART, strophanthus, effectual action of, by inhalation, (106) 738
strophanthus in insomnia from disease of, (138) 1853
strychnin and caffein as stimulants (3) 880
thermal baths, action of, on blood-vessels and, (122) 1853
tricuspid, congenital atresia of, (77) 1201
valve, diagnosis of insufficiency of pulmonary, (82) 889
valves, operations on, (76) 1203, (93) 1204
valvular defect, developmental, (159) 172
valvular disease, chronic, (11) 575
valvular lesions, how developed, (48) 972
wounds, operative treatment of, (69) 1512
HEAT and infant mortality, 158—ab, (33) 488
effect of, on blood-pressure, (32) 808
enhanced toxicity of cholera toxins in animals under influence of humidity and, (182) 173
in cancer, 405—ab, *1631
influence of air, light and, on heart disease, (93) 419
method of sterilizing and storing catgut, simple, (121) 1929
prostration, (85) 1755
regulation of, influence of nervous system on metabolism and, (116) 1058
stroke, mechanism of, (146) 421
stroke, treatment, (71) 578
HEATH mastoid operations, experiences with, (91) 1507
HEBRA panacea, (135) 164
HEDONAL, intravenous, general anesthesia with, experimental research on, (55) 415
HEIGHT standard in Austro-Hungarian army and navy, diminution of, 947
HELIOTHERAPY: See Sunlight Therapy
HELLER-DOEHLE'S aortitis, dilatation of aorta in, (75) 1366
HELMINTHIASIS, serodiagnosis of cancer and, (128) 1443
teething and growing pains, (38) 577
treatment, (43) 886
HEMANGIO-ENDOTHELIOMA from dura of frontal region of brain, successful removal of, (9) 1431
HEMARTHROSIS, crucial ligaments in, and injuries to knee, (29) 1847
HEMATEMESIS, abscess caused by fish-bone with, hot water for, *375
with cirrhosis, liver insufficiency in, (79) 495
HEMATOPORPHYRIN of blood and bile, sensitizing effect of, (107) 245
HEMATURIA after hexamethylenamin, four cases, (137) 1591
essential, (102) 333, (118) 1287
local, circumscribed, hyaline degeneration in kidney, cause of, (127) 339
pathologic and diagnostic import of, (109) 1435
renal with three anomalous renal arteries, (99) 1845
significance of, its management, (11) 159
unilateral, severe, without evident cause, (21) 1694
with appendicitis, (36) 1125
HEMAUROCHROME reaction, *1807
reaction of T. J. Davis, *1807
HEMERALOPIA, acute, (125) 976
HEMIANOPSIA, anemia with aphasia and, severe, (97) 244
binasal, occurring in the course of optic atrophy, due to tabes dorsalis, *771
HEMIATROPHY, facial, case of, (79) 1434
HEMIPLEGIA due to pneumonia, (14) 728
loss of hemiopic lid reflex in, (57) 652
muscles, weakness of, on paralyzed side only sign of organic nature of, (144) 1060
postoperative, two cases, (46) 493
transient, (15) 1051
HEMITERATA and terata, teaching classification for, (110) 1199
HEMO-ANGIOMA, breast, (175) 500
HEMOCYTOMETER, standardization of bacterial vaccines by Wright plate culture methods and, (25) 1124
HEMOGLOBIN scale, improved, (139) 1294, (74) 1366
HEMOGLOBINEMIA, production of general symptoms in, (3) 733
HEMOGLOBINURIA, Malarial: See Blackwater Fever
HEMOGLOBINURIA, paroxysmal, *356
paroxysmal, auto-anaphylaxis as explanation of, (48) 415
paroxysmal, due to cold, clinical and serologic study of, (115) 582
paroxysmal, idiopathic, (184) 1209
paroxysmal, pathology and treatment, (92) 418
unusual type, (80) 811
HEMOGREGARINE, life cycle of, found in Monitor (veranus niloticus), (70) 647
HEMOLYMPH-GLANDS, 1968—E
HEMOLYSIN of bacillus subtilis, (185) 342
HEMOLYSIS due to intravenous injection of distilled water, *992
HEMOPHILIA, blood condition in, (25) 488
clinical and experimental study of, (86) 1851
dry diet in, (193) 83
familial, danger of injections of Witte peptone in, (50) 1511
joint lesions, chronic, in, (27) 1052
kidney hemorrhage in, (193) 83
HEMOPNEUMOTHORAX, spontaneous, (19) 333
HEMOPTYSIS, artificial pneumothorax in, (26) 492, 564—ab
emetin in, (154) 740, (30) 813
pituitary extract in, (143) 1766
salt solution, intravenous injection of 10 per cent., to arrest, (108) 1935
serotherapy for, (193) 174
treatment of, (116) 1205
HEMORENAL index of kidney functioning, (62) 166, (75) 737
HEMORRHAGE, accidental concealed, accompanied by intraperitoneal hemorrhage, (27) 1200
acute hemorrhagic encephalitis in pons with fatal, (157) 1951
ante-partum, cesarean section in, (117) 967
artery, minute, in hemorrhoids, (92) 244
brain, after rachicentesis, (163) 248
brain, decompressive trephining in, 560—ab
brain, diagnosis of, (129) 1591
brain, treatment, (112) 245
brain, venesection in, (80) 410
calomel injections followed by multiple, (165) 1699
cerebral decompressive trephining on sound side in certain cases of, (69) 76
cerebral, in chronic myeloid leukemia, (44) 735
cerebral, onset and character of apoplexy from vascular occlusion and, *1385
cerebral, spontaneous, on eighth day of acute hemorrhagic diathesis, (131) 1853
edema and, from poisons, (125) 1443
epigastric artery, secondary, after operations for appendix abscess, (47) 493
esophageal vein, ruptured normal horse serum in, (27) 1048
fat graft to arrest, (197) 83, (49) 1289
from myomas cured by removal of ovaries, (83) 1696
gastro-intestinal, in two newborn infants, (59) 578
gastro-intestinal, iodin in, (120) 245
gastro-intestinal, permanent impairment of vision following, (32) 1753
in pregnancy, threatening, (92) 1852
in spinal canal in newborn infant, (140) 421
in tonsil and adenoid operations, (6) 885, (28) 1358, (84) 1360
intracranial, decompression of brain in, (23) 1052
intracranial, in new-born infant, (9) 1583
intraperitoneal, with leukocytosis, (142) 1698
kidney, (74) 1849
kidney in hemophiliacs, (193) 83

GRAFTING tissue, heteroplastic, source of defense in, *199, (63) 1927
  urethra, experimental, (219) 84
  vascular, 1581—ab
  vein to form new common bile duct, (140) 819
GRAM stain, simplification of, *1251
GRAND prix for sale, 866—P
GRANULATIONS, protection of, by new dressing material, *1247
GRANULOMA, epithelioma of hand following trauma, resembling, 1838—ab
  malignant, (156) 1516
  tropical, infective, etiology of, 37—ab
GRAPE juice, (108) 1130
GRAVES' DISEASE: See Goiter, Exophthalmic
GREAT LAKES, water supply of ships on, 1116—ab
GREEN operating-room at St. Luke's hospital, (49) 1754
GRIFFITH article on orthopedic surgery, correction of error in, 1348—C
GROIN, pain in, in young men, (112) 891
GROWING pains, helminthiasis and teething, (33) 577
GROWTH and ductless glands, relationship of, (107) 1755
  and fatigue, (38) 645
  and food, (17) 2052
  defective, in relatives investigated by roentgenoscopy, (3) 333
  influence of diet on normal and malignant, (43) 493
  of birds, early, and anterior lobe of hypophysis, (1) 1840
  of young animals, effect of pituitary extract on human blood-pressure and, (73) 1128
GRUEL, malted, for sick infants, advantages of, (60) 736
GUAIAC TEST: See Test, Guaiac
GUAIACOL in lung tuberculosis, administration of, (17) 492
  poisoning by absorption, (41) 1754
GUARANTY of cure, money paid for treatment and medicine recoverable on breach of, 959—Ml
GUARD, spiral spring, for catheter, (130) 1131
GUITERAS called to Tampico, 1671
GUMMA of tongue, salvarsan therapy in, results, (108) 163
GUMS, giant-cell endothelioma of, and formation of giant-cells in same and in tuberculosis and blastomycosis, (69) 647
  soreness of tongue and, periodical, early symptom of pernicious anemia, (28) 160
GYNATRESIA during pregnancy, (37) 1289
GYNECOLOGY, America's contribution to, (20) 1431
  contributions to, during 1913, important, (22) 571
  diagnosis in, tonus of uterus cervix as aid, (48) 652
  ether dressings in, (88) 1203
  eugenics and, (147) 80, (1117) 1205
  examination in, (103) 1199
  examination in obstetrics and, credits in, (154) 499
  general practitioner and, (111) 1130
  general rather than local causes in gynecologic disorders, (23) 408
  mesothorium in, (46) 2054
  nascent formaldehyd in, (70) 495
  operations, fatalities following, at Basel, 1901-1911, (167) 81
  operations, 524, ultimate outcome of, (166) 173
  pituitary extract in, (42) 1587
  place of, in medical school and general practice, (16) 1200
  preservation of physiologic functions in, (53) 1994
  progress in, (30) 1586
  psychiatry and, (106) 1442
  puncture as curative measure in, (149) 1444
  radiotherapy, (90) 737, (91) 889
  radium and roentgenotherapy in, older and newer treatment, (103) 1928
  reforms needed in practice of, (129) 73
  roentgenotherapy (75) 77, (8) 329, (131) 339, (104) 890, (90) 1037, (155) 1361
  roentgenotherapy and mesothorium in, (15) 1047
  roentgenotherapy and radium therapy in, (90) 1367
GYNECOLOGY, roentgenotherapy in, exophthalmic goiter as contra-indication for, (118) 1131
  roentgenotherapy in, technic for and advantages of, (202) 88
  serodiagnosis in, (84) 974
  spinal anesthesia in, (5) 1753, 2047—ab
  tampon in obstetrics and, (114) 890

H

HABIT forming drugs, Harrison bills and Nelson amendment on, 1276—ME
HAHNEMANN Medical College of Philadelphia elected to membership in Association of American Medical Coleges, 720
HAINES' method of operation in purulent meningitis, (93) 163
HAIR, albinism of eyes without involvement of skin or, (116) 1845
  and fur dyes, dermatoses from, (119) 245
  balls of stomach and intestine, *107
  blanching of, sudden, 1982—C
  color of eyes and, in Norway, (206) 1210
  follicles, destruction of sebaceous glands, sweat glands and, by Roentgen rays, (39) 1843
  growth and color changes of, 1726—E
  internal secretion, effect of, on development and dentition and, (205) 1210, 1334—E, (86) 1441
  pathology of, connection between genital development and, (47) 887
  removing, from field of operation, improved technic for, (175) 1700
HALE, W. H., quack and jail bird, 143—P
HALLUCINOSIS, study of, (9) 1688
HAMBURGER steak, bacteriologic analysis of, with reference to sanitary standards, (18) 1925
HAMBURGISCHE medicinische Ueberseehefte, new journal, 1814—E
HANDS, blood-flow in feet and, in cases with obvious anatomic differences, (31) 69
  blood-flow in feet and, in diseased conditions of blood-vessels, (28) 808
  blood-flow in, in heart diseases, (22) 487
  disinfection of, 717
  eczema, roentgenotherapy in, (67) 237
  epithelioma of, traumatic resembling granuloma, 1838—ab
  flexor tendons of, repair of, revised technic, (42) 241
  neural atrophy of small muscles of, without sensory disturbances, 727—ab
  sand better than brush for cleaning, (114) 420
  sterilization of, alcohol in, (143) 1443
  sterilization of, and field of operation, (150) 1766
  sterilization of field and, superiority of 5 per cent. alcoholic solution of thymol over tincture of iodin for, (208) 84
  tuberculosis and cancer on back of, (36) 1931
HARELIP, (59) 1286
  and cleft palate, treatment, (67) 653, (32) 886
HARRISON bills and Nelson amendment for regulation of traffic in habit-forming drugs, 1276—ME
  opium bills, 316—ME
HARTEL'S method of intraganglionic injection of alcohol for trifacial neuralgia, (37) 160

  expert, second tentative report of committee of American Medical Association on, 723—ab
  medical and lay, relative weight of, as to mental capacity, 1045—Ml
  medical and legal supervision, (42) 1584
  of physicians as witness and expert, (121) 1697
TETANUS, (127) 170, 1964—T
  acute, with recovery (16) 885
  antitoxin, 128, 931, 1890, *2025
  Ashhurst and John rational method of treatment, *191
  Kintzing treatment of, 1190
  magnesium sulphate, intraspinal injections of, in treatment of, (53) 1438
  phenol, intravenous injections of, (196) 1210, (26) 1996
  prophylaxis of, 1971—E
  serotherapy of, (180) 249, (136) 740, 1174—E
  traumatic and inflammatory origin, operative treatment, (84) 737
TETANY, (106) 411
  asthma with, calcium treatment, (90) 974
  chronic, after removal of parathyroid glands in animals, (139) 1698
  gastric, (12) 240, *590
  in dogs, (57) 331
  postoperative, organ therapy and prophylaxis of, (137) 1698
TETRAGENUS sepsis, recovery, (132) 1765
TEXAS Christian University Medical Department of Fort Worth raised to class B, 1577
  medical news, 138, 390, 467, 708, 1029, 1412, 1486, 1735, 1976
  state board June report, 636
  state board November report 1577
THALASSOTHERAPY, International Congress on, 628
THALLOPHYTIC fungus, extirpation of bacillus diphtheria by, (67) 410
THEOBROMIN, action of sodium salicylate and, on edema, (84) 495
  sodium salicylate versus diuretin, the economical aspect, 1108—P
THERMOCAUTERY in erysipelas, (55) 1998
THERMOPENETRATION, (146) 1206
  in lung tuberculosis, therapeutic effects of, (2) 643
THERMOPRECIPITIN reaction in diagnosis of lung tuberculosis, (47) 1202, 1350
THERMOTHERAPY in gonorrhea, (82) 816
THIERSCH *and Cohnheim, theory* of, on cancer, *977
  flaps, cork paper for protection of (149) 499
THINKING, autistic, (5) 1503
THIOCOL and syrup thiocol, Roche, 1637
THOMPSON-M'FADDEN Pellagra Commission, reoprt of, *8
THOMSEN'S Disease: See Myotonia Congenita
THORACIC DUCT, tampon buried in, to plug fistula in, (135) 1131
  varices in, (99) 1764
THORAX abscess, in children, roentgenoscopy of, (128) 421
  anatomic changes in organs in *abdomen and, after intraperitoneal* injection of camphorated oil, (70) 243
  apparatus for use in operations on, (41) 1358
  auscultation of, transmission of tuning-fork note through, (144) 421
  diagnosis of diseases, common mistakes in, (3) 885
  emphysema, subcutaneous, of face, neck, and, during labor, (5) 649
  fascia flaps to close defects in wall of, and re-enforce suture of lung, (101) 78
  flat diagram of, (86) 496
  fluctuation in pressure in, aid to circulation, (96) 241
  hypernephroma with metastasis in, (17) 1583
  operation on costal cartilage to mobilize wall of, (80) 1203
  palpation and inspection of, in diagnosis of pulmonary tuberculosis, (42) 1932
  percussion, control of, with *Roentgen ray, (21) 645*
  predisposing to disease, attitude of, (140) 498
  predisposing to tuberculosis, shape of, operative treatment of apical tuberculous process, (85) 418
  roentgenoscopy of suppurative processes in, (77) 1512
  sarcoma, (23) 159
  surgery of (37) 734, (150) 819
  tuberculous lymph-nodes in, (195) 1210
  tumors, (58) 652
  tuning-fork in diagnosing outlines of solid and hollow viscera of abdomen and, and of certain pathologic conditions, (22) 650
THORIUM X in pernicious anemia, (70) 816
  treatment in internal diseases, (123) 656
THOXOS, 949—P
THREAD and benzidin test for ulcer of stomach, 1275
  test, of conditions in stomach, (74) 579, (100) 890
THREADWORMS: See Oxyuris *Vermicularis*
THROAT and ear complication of leukemia and pseudoleukemia, (112) 648
  apparatus for protection against, infection in examinations of nose and, *454
  conservation of functions of ear, nose and, (108) 1199
  examination, importance of, (27) 1996
  examinations of nose and, in institution for delinquent boys, (34) 1048
  herpes in, (146) 1060
  in exophthalmic goiter, (64) 1927
  intratracheal anesthesia from standpoint of surgeon, (101) 163
  joint disease merely expression of chronic infectious process in nose, ear or, (87) 245
  nascent iodin in ear and, (71) 1203
  nose, eye and ear work, accessory facts to, of interest to physicians, (132) 649
  pathologic conditions in, reflex to disease of teeth, jaws or parotid gland, (21) 1048
  quinin and urea hydrochlorid in surgery, of (49) 1048
  septic sore epidemic due to milk supply, etiology of, 853—E
  septic sore, epidemic in Cortland and Homer, N. Y., probably due to milk, (35) 572
  sore, syphilitic, diagnosed as *diphtheria, subsequent eruption* confused with antitoxic erythema, *1013
  streptococcic disease, (127) 1199
  systemic diseases and diseases of eye, ear, nose and, interrelation between, (99) 1122
THROAT, tuberculosis of nose and, ions in, (192) 342
  tuberculous cervical adenitis, in relation to diseases of nose and (44) 1359
  violet ray and ozone of use in diseases of ear, nose and, (71) 811
THROMBOPHLEBITIS of left femoral vein complicating typhoid spine, (87) 490
  septic, of pelvic veins, (60) 1843
THROMBOSIS and embolism following abdominal operations and labor, (62) 883
  blood condition in, (25) 488
  heart, aortic embolism, mitral stenosis and gangrene of both legs, case of, (20) 885
  mesenteric vein, (44) 2054
  mesenteric vein with latent sclerosis of portal vein, (72) 973
  pneumococcus, of cerebral arteries, (71) 1695
  prophylaxis of, (129) 339
  question of, (99) 654
  septic, of lateral sinus, (16) 1195
  sinus, cavernous, (96) 163
  sinus, cavernous, due to streptothrix, (6) 1195
  vein, central, of retina, (34) 1931
  venous, *latent pulmonary embolism* and infarction from, causing pulmonary attack simulating lobar pneumonia, (23) 1195
THUMB, deformed, correction of, (61) 1587
THYMOL, superiority of 5 per cent. alcoholic solution of, over tincture of iodin for sterilization of hands and field, (208) 84
THYMUS: See also Goiter; Status Lymphaticus
THYMUS, (96) 1360
  and thyroid in relation to growth, 2033—E
  chemical composition of, (69) 336
  diagnosis of enlarged, and symptomatology of hyper-thymatism, (31) 1358
  effect of early extirpation of, in albino rats, (59) 1359
  enlargement of, lymphatism, and *shock, relation between, (5)* 880
  extract, effects of, experimental study of, (105) 1589, (118) 1853
  extracts, inconstant effect of, (91) 1292
  function of, (134) 1765
  hyperplasia, operative treatment, (99) 419
  in exophthalmic goiter, (51) 814, 1822
  in exophthalmic goiter, origin and course of, importance of, (69) 1850
  in thyroid disease, (121) 1368
  ovaries and blood picture, (108) 420
  pathologic and clinical study, (90) 419
  relation between thyroid, parathyroids and, shown by Abderhalden's dialysis, (137) 819
  roentgenotherapy of enlarged, (9) 329
THYREOPATHIES, commoner, diagnosis and treatment, (141) 491
  weight of, of albino rat, (4) 1991
THYROGLOSSAL cyst and fistula, (175) 1756
  tract, (20) 1052
THYROID: See also Goiter; Parathyroid
THYROID, accessory, removal of, *technic, (56) 415*
  and antitoxin, (29) 335
  and deforming arthritis, (144) 892
  and thymus in relation to growth, 2033—E
  antitoxic influence of, (187) 1757
  artery, superior, exophthalmic goiter cured by ligating one, (109) 731
  cancer, (107) 78, (47) 814
  cartilage, perichondritis of the, (128) 818
  cysts, 1822
  desiccated, forms of urinary nitrogen affected by administration of, to dementia praecox patients, (35) 69
  diarrhea originating in, (72) 1056
  disease, iodin in, (103) 419
  disease, lack or excess of iodin in, (110) 1697
  disease, 23 cases of, (105) 72
  disease, thymus with, (121) 1368
